VERSION 10.0.5, May 5, 2025

## Abstract

SuiteSparse:GraphBLAS is a full implementation of the GraphBLAS standard, which defines a set of sparse matrix operations on an extended algebra of semirings using an almost unlimited variety of operators and types. When applied to sparse adjacency matrices, these algebraic operations are equivalent to computations on graphs. GraphBLAS provides a powerful and expressive framework for creating high-performance graph algorithms based on the elegant mathematics of sparse matrix operations on a semiring.

When compared with MATLAB R2021a, some methods in GraphBLAS are up to a million times faster than MATLAB, even when using the same syntax. Typical speedups are in the range 2x to 30x. The statement  $\mathbf{C}(\mathbf{M})=\mathbf{A}$  when using MATLAB sparse matrices takes  $O(e^2)$  time where  $e$  is the number of entries in  $\mathbf{C}$ . GraphBLAS can perform the same computation with the exact same syntax, but in  $O(e \log e)$  time (or  $O(e)$  in some cases), and in practice that means GraphBLAS can compute  $\mathbf{C}(\mathbf{M})=\mathbf{A}$  for a large problem in under a second, while MATLAB takes about 4 to 5 days.

SuiteSparse:GraphBLAS is under the Apache-2.0 license.

# Contents

<b>1</b>	<b>Introduction</b>	<b>13</b>
<b>2</b>	<b>Basic Concepts</b>	<b>14</b>
2.1	Graphs and sparse matrices . . . . .	14
2.2	Overview of GraphBLAS methods and operations . . . . .	16
2.3	The accumulator and the mask . . . . .	19
2.4	Typecasting . . . . .	23
2.5	Notation and list of GraphBLAS operations . . . . .	24
<b>3</b>	<b>Changes in GraphBLAS v10: 32/64 bit integers</b>	<b>26</b>
3.1	Controlling the sizes of integers . . . . .	26
3.2	Passing arrays to/from GraphBLAS . . . . .	26
3.3	Container methods: loading/unloading data to/from a matrix or vector . . . . .	29
3.4	Historical methods: pack/unpack . . . . .	30
<b>4</b>	<b>Interfaces to MATLAB, Octave, Python, Julia, Go, Java, ...</b>	<b>32</b>
4.1	MATLAB/Octave Interface . . . . .	32
4.2	Performance of MATLAB versus GraphBLAS . . . . .	33
4.3	Python Interface . . . . .	35
4.4	Julia Interface . . . . .	35
4.5	Go Interface . . . . .	35
4.6	Java Interface . . . . .	35
<b>5</b>	<b>GraphBLAS Initialization/Finalization</b>	<b>36</b>
5.1	GrB_Index: the GraphBLAS integer . . . . .	38
5.2	GrB_init: initialize GraphBLAS . . . . .	38
5.3	GrB_getVersion: determine the C API Version . . . . .	40
5.4	GxB_init: initialize with alternate malloc . . . . .	40
5.5	GrB_Info: status code returned by GraphBLAS . . . . .	41
5.6	GrB_error: get more details on the last error . . . . .	42
5.7	GrB_finalize: finish GraphBLAS . . . . .	43
<b>6</b>	<b>GraphBLAS Objects and their Methods</b>	<b>44</b>
6.1	The GraphBLAS type: GrB_Type . . . . .	45
6.1.1	GrB_Type_new: create a user-defined type . . . . .	46
6.1.2	GxB_Type_new: create a user-defined type (with name and definition) . . . . .	47
6.1.3	GrB_Type_wait: wait for a type . . . . .	48

6.1.4	GxB_Type_from_name: return the type from its name . . . . .	49
6.1.5	GrB_Type_free: free a user-defined type . . . . .	50
6.2	GraphBLAS unary operators: GrB_UnaryOp, $z = f(x)$ . . . . .	51
6.2.1	GrB_UnaryOp_new: create a user-defined unary operator . . . . .	54
6.2.2	GxB_UnaryOp_new: create a named user-defined unary operator . . . . .	55
6.2.3	GrB_UnaryOp_wait: wait for a unary operator . . . . .	56
6.2.4	GrB_UnaryOp_free: free a user-defined unary operator . . . . .	56
6.3	GraphBLAS binary operators: GrB_BinaryOp, $z = f(x, y)$ . . . . .	57
6.3.1	GraphBLAS binary operators based on index binary operators . . . . .	60
6.3.2	GrB_BinaryOp_new: create a user-defined binary operator . . . . .	62
6.3.3	GxB_BinaryOp_new: create a named user-defined binary operator . . . . .	63
6.3.4	GrB_BinaryOp_wait: wait for a binary operator . . . . .	64
6.3.5	GrB_BinaryOp_free: free a user-defined binary operator . . . . .	64
6.3.6	ANY and PAIR (ONEB) operators . . . . .	64
6.4	GraphBLAS IndexUnaryOp operators: GrB_IndexUnaryOp . . . . .	66
6.4.1	GrB_IndexUnaryOp_new: create a user-defined index-unary operator . . . . .	68
6.4.2	GxB_IndexUnaryOp_new: create a named user-defined index-unary operator . . . . .	69
6.4.3	GrB_IndexUnaryOp_wait: wait for an index-unary operator . . . . .	70
6.4.4	GrB_IndexUnaryOp_free: free a user-defined index-unary operator . . . . .	71
6.5	GraphBLAS index-binary operators: GxB_IndexBinaryOp . . . . .	72
6.5.1	GxB_IndexBinaryOp_new: create a user-defined index-binary operator . . . . .	74
6.5.2	GxB_IndexBinaryOp_wait: wait for an index-binary operator . . . . .	76
6.5.3	GxB_IndexBinaryOp_free: free a user-defined index-binary operator . . . . .	76
6.5.4	GxB_BinaryOp_new_IndexOp: create a index-based binary operator . . . . .	77
6.6	GraphBLAS monoids: GrB_Monoid . . . . .	78
6.6.1	GrB_Monoid_new: create a monoid . . . . .	80
6.6.2	GrB_Monoid_wait: wait for a monoid . . . . .	80
6.6.3	GxB_Monoid_terminal_new: create a monoid with terminal . . . . .	81
6.6.4	GrB_Monoid_free: free a monoid . . . . .	82
6.7	GraphBLAS semirings: GrB_Semiring . . . . .	83
6.7.1	GrB_Semiring_new: create a semiring . . . . .	83
6.7.2	GrB_Semiring_wait: wait for a semiring . . . . .	85

6.7.3	GrB_Semiring_free: free a semiring . . . . .	85
6.8	GraphBLAS scalars: GrB_Scalar . . . . .	86
6.8.1	GrB_Scalar_new: create a scalar . . . . .	86
6.8.2	GrB_Scalar_wait: wait for a scalar . . . . .	86
6.8.3	GrB_Scalar_dup: copy a scalar . . . . .	87
6.8.4	GrB_Scalar_clear: clear a scalar of its entry . . . . .	87
6.8.5	GrB_Scalar_nvals: return the number of entries in a scalar . . . . .	88
6.8.6	GrB_Scalar_setElement: set the single entry of a scalar . . . . .	88
6.8.7	GrB_Scalar_extractElement: get the single entry from a scalar . . . . .	89
6.8.8	GxB_Scalar_memoryUsage: memory used by a scalar . . . . .	89
6.8.9	GxB_Scalar_type: type of a scalar . . . . .	89
6.8.10	GrB_Scalar_free: free a scalar . . . . .	90
6.9	GraphBLAS vectors: GrB_Vector . . . . .	91
6.9.1	GrB_Vector_new: create a vector . . . . .	92
6.9.2	GrB_Vector_wait: wait for a vector . . . . .	92
6.9.3	GrB_Vector_dup: copy a vector . . . . .	93
6.9.4	GrB_Vector_clear: clear a vector of all entries . . . . .	93
6.9.5	GrB_Vector_size: return the size of a vector . . . . .	94
6.9.6	GrB_Vector_nvals: return the number of entries in a vector . . . . .	94
6.9.7	GrB_Vector_build: build a vector from a set of tuples . . . . .	94
6.9.8	GrB_Vector_build_Vector: build a vector from a set of tuples . . . . .	95
6.9.9	GxB_Vector_build_Scalar: build a vector from a set of tuples . . . . .	95
6.9.10	GxB_Vector_build_Scalar_Vector: build a vector from a set of tuples . . . . .	96
6.9.11	GrB_Vector_setElement: add an entry to a vector . . . . .	96
6.9.12	GrB_Vector_extractElement: get an entry from a vector . . . . .	97
6.9.13	GxB_Vector_isStoredElement: check if entry present in vector . . . . .	97
6.9.14	GrB_Vector_removeElement: remove an entry from a vector . . . . .	97
6.9.15	GrB_Vector_extractTuples: get all entries from a vector . . . . .	98
6.9.16	GxB_Vector_extractTuples_Vector: get all entries from a vector . . . . .	98
6.9.17	GrB_Vector_resize: resize a vector . . . . .	99
6.9.18	GxB_Vector_diag: extract a diagonal from a matrix . . . . .	99
6.9.19	GxB_Vector_memoryUsage: memory used by a vector . . . . .	100
6.9.20	GxB_Vector_type: type of a vector . . . . .	100
6.9.21	GrB_Vector_free: free a vector . . . . .	100
6.10	GraphBLAS matrices: GrB_Matrix . . . . .	101
6.10.1	GrB_Matrix_new: create a matrix . . . . .	102
6.10.2	GrB_Matrix_wait: wait for a matrix . . . . .	103
6.10.3	GrB_Matrix_dup: copy a matrix . . . . .	103
6.10.4	GrB_Matrix_clear: clear a matrix of all entries . . . . .	104

6.10.5	GrB_Matrix_nrows: return the number of rows of a matrix .	104
6.10.6	GrB_Matrix_ncols: return the number of columns of a matrix	104
6.10.7	GrB_Matrix_nvals: return the number of entries in a matrix .	105
6.10.8	GrB_Matrix_build: build a matrix from a set of tuples . . . .	105
6.10.9	GxB_Matrix_build_Vector: build a matrix from a set of tuples	107
6.10.10	GxB_Matrix_build_Scalar: build a matrix from a set of tuples	108
6.10.11	GxB_Matrix_build_Scalar_Vector: build a matrix from a set of tuples . . . . .	108
6.10.12	GrB_Matrix_setElement: add an entry to a matrix . . . . .	109
6.10.13	GrB_Matrix_extractElement: get an entry from a matrix . . .	110
6.10.14	GxB_Matrix_isStoredElement: check if entry present in matrix	111
6.10.15	GrB_Matrix_removeElement: remove an entry from a matrix	112
6.10.16	GrB_Matrix_extractTuples: get all entries from a matrix . . .	112
6.10.17	GxB_Matrix_extractTuples_Vector: get all entries from a matrix	113
6.10.18	GrB_Matrix_resize: resize a matrix . . . . .	113
6.10.19	GxB_Matrix_reshape: reshape a matrix . . . . .	114
6.10.20	GxB_Matrix_reshapeDup: reshape a matrix . . . . .	115
6.10.21	GxB_Matrix_concat: concatenate matrices . . . . .	115
6.10.22	GxB_Matrix_split: split a matrix . . . . .	116
6.10.23	GrB_Matrix_diag: construct a diagonal matrix . . . . .	116
6.10.24	GxB_Matrix_diag: build a diagonal matrix . . . . .	117
6.10.25	GxB_Matrix_memoryUsage: memory used by a matrix . . . .	117
6.10.26	GxB_Matrix_type: type of a matrix . . . . .	118
6.10.27	GrB_Matrix_free: free a matrix . . . . .	118
6.11	Serialize/deserialize methods . . . . .	119
6.11.1	GxB_Vector_serialize: serialize a vector . . . . .	121
6.11.2	GxB_Vector_deserialize: deserialize a vector . . . . .	121
6.11.3	GrB_Matrix_serializeSize: return size of serialized matrix . .	122
6.11.4	GrB_Matrix_serialize: serialize a matrix . . . . .	122
6.11.5	GxB_Matrix_serialize: serialize a matrix . . . . .	123
6.11.6	GrB_Matrix_deserialize: deserialize a matrix . . . . .	123
6.11.7	GxB_Matrix_deserialize: deserialize a matrix . . . . .	124
6.12	The GxB.Container object and its methods . . . . .	125
6.12.1	GxB_Vector_load: load data into a vector . . . . .	126
6.12.2	GxB_Vector_unload: unload data from a vector . . . . .	127
6.12.3	GxB.Container_new: create a container . . . . .	128
6.12.4	GxB.Container_free: free a container . . . . .	130
6.12.5	GxB_load_Matrix_from_Container: load a matrix from a con- tainer . . . . .	130
6.12.6	GxB_load_Vector_from_Container: load a vector from a container	130

6.12.7	GxB_unload_Matrix_into_Container: unload a matrix into a container . . . . .	131
6.12.8	GxB_unload_Vector_into_Container: unload a vector into a container . . . . .	131
6.12.9	Container example: unloading/loading an entire matrix into C arrays . . . . .	131
6.12.10	Container example: unloading/loading, but not using C arrays	134
6.13	SuiteSparse:GraphBLAS data formats . . . . .	135
6.13.1	Sparse, held by row . . . . .	135
6.13.2	Sparse, held by column . . . . .	137
6.13.3	Hypersparse, held by row . . . . .	138
6.13.4	Hypersparse, held by column . . . . .	140
6.13.5	Bitmap, held by row . . . . .	140
6.13.6	Bitmap, held by column . . . . .	140
6.13.7	Full, held by row . . . . .	140
6.13.8	Full, held by column . . . . .	141
6.14	GraphBLAS import/export: using copy semantics . . . . .	142
6.14.1	GrB_Matrix_import: import a matrix . . . . .	143
6.14.2	GrB_Matrix_export: export a matrix . . . . .	144
6.14.3	GrB_Matrix_exportSize: determine size of export . . . . .	145
6.14.4	GrB_Matrix_exportHint: determine best export format . . . . .	145
6.15	Sorting methods . . . . .	146
6.15.1	GxB_Vector_sort: sort a vector . . . . .	146
6.15.2	GxB_Matrix_sort: sort the rows/columns of a matrix . . . . .	146
6.16	GraphBLAS descriptors: GrB_Descriptor . . . . .	148
6.16.1	GrB_Descriptor_new: create a new descriptor . . . . .	152
6.16.2	GrB_Descriptor_wait: wait for a descriptor . . . . .	152
6.16.3	GrB_Descriptor_free: free a descriptor . . . . .	153
6.16.4	Descriptor settings for GrB_Vector parameters . . . . .	153
6.16.5	GrB_DESC_*: built-in descriptors . . . . .	155
6.17	GrB_free: free any GraphBLAS object . . . . .	156
<b>7</b>	<b>The mask, accumulator, and replace option</b>	<b>157</b>
<b>8</b>	<b>GxB_Context: controlling computational resources</b>	<b>160</b>
8.1	GxB_Context_new: create a new context . . . . .	162
8.2	GxB_Context_engage: engaging context . . . . .	162
8.3	GxB_Context_disengage: disengaging context . . . . .	163
8.4	GxB_Context_free: free a context . . . . .	163
8.5	GxB_Context_wait: wait for a context . . . . .	164

<b>9</b>	<b>The SuiteSparse:GraphBLAS JIT</b>	<b>165</b>
9.1	Using the JIT . . . . .	165
9.1.1	GxB_JIT_C_CONTROL . . . . .	166
9.1.2	JIT error handling . . . . .	167
9.1.3	GxB_JIT_C_COMPILER_NAME . . . . .	169
9.1.4	GxB_JIT_C_COMPILER_FLAGS . . . . .	169

10.9	GrB_Semiring Options . . . . .	199
10.10	GrB_Matrix Options . . . . .	201
10.10.1	Storing a matrix by row or by column . . . . .	202
10.10.2	Hypersparse matrices . . . . .	203

10.10.3	Bitmap matrices	205
10.10.4	Sparsity status	206
10.10.5	iso status	207
10.10.6	wait status	207
10.11	GrB_Vector Options	208
10.12	GrB_Scalar Options	209
10.13	Controlling the sizes of integers	209
10.14	GrB_Descriptor Options	211
10.15	GxB_Context Options	213
10.16	Options for inspecting a serialized blob	214
<b>11</b>	<b>SuiteSparse:GraphBLAS Colon and Index Notation</b>	<b>215</b>
<b>12</b>	<b>GraphBLAS Operations</b>	<b>220</b>
12.1	GrB_mxm: matrix-matrix multiply	221
12.2	GrB_vxm: vector-matrix multiply	223
12.3	GrB_m xv: matrix-vector multiply	224
12.4	GrB_eWiseMult: element-wise operations, set intersection	225
12.4.1	GrB_Vector_eWiseMult: element-wise vector multiply	226
12.4.2	GrB_Matrix_eWiseMult: element-wise matrix multiply	227
12.5	GrB_eWiseAdd: element-wise operations, set union	228
12.5.1	GrB_Vector_eWiseAdd: element-wise vector addition	229
12.5.2	GrB_Matrix_eWiseAdd: element-wise matrix addition	230
12.6	GxB_eWiseUnion: element-wise operations, set union	231
12.6.1	GxB_Vector_eWiseUnion: element-wise vector addition	232
12.6.2	GxB_Matrix_eWiseUnion: element-wise matrix addition	233
12.7	GrB_extract: submatrix extraction	234
12.7.1	GrB_Vector_extract: extract subvector from vector	234
12.7.2	GxB_Vector_extract_Vector: extract subvector from vector	234
12.7.3	GrB_Matrix_extract: extract submatrix from matrix	235
12.7.4	GxB_Matrix_extract_Vector: extract submatrix from matrix	236
12.7.5	GrB_Col_extract: extract column vector from matrix	236
12.7.6	GxB_Col_extract_Vector: extract column vector from matrix	237
12.8	GrB_assign: submatrix assignment	238
12.8.1	GrB_Vector_assign: assign to a subvector	238
12.8.2	GxB_Vector_assign_Vector: assign to a subvector	238
12.8.3	GrB_Matrix_assign: assign to a submatrix	239
12.8.4	GxB_Matrix_assign_Vector: assign to a submatrix	240
12.8.5	GrB_Col_assign: assign to a sub-column of a matrix	241
12.8.6	GxB_Col_assign_Vector: assign to a sub-column of a matrix	241

12.8.7	GrB_Row_assign: assign to a sub-row of a matrix . . . . .	242
12.8.8	GxB_Row_assign_Vector: assign to a sub-row of a matrix . . .	243
12.8.9	GrB_Vector_assign_<type>: assign a scalar to a subvector . . .	243
12.8.10	GxB_Vector_assign_Scalar_Vector: assign a scalar to a subvector	244
12.8.11	GrB_Matrix_assign_<type>: assign a scalar to a submatrix . . .	244
12.8.12	GxB_Matrix_assign_Scalar_Vector: assign a scalar to a submatrix	245
12.9	GxB_subassign: submatrix assignment . . . . .	247
12.9.1	GxB_Vector_subassign: assign to a subvector . . . . .	247
12.9.2	GxB_Vector_subassign_Vector: assign to a subvector . . . . .	248
12.9.3	GxB_Matrix_subassign: assign to a submatrix . . . . .	248
12.9.4	GxB_Matrix_subassign_Vector: assign to a submatrix . . . . .	250
12.9.5	GxB_Col_subassign: assign to a sub-column of a matrix . . . .	251
12.9.6	GxB_Col_subassign_Vector: assign to a sub-column of a matrix	251
12.9.7	GxB_Row_subassign: assign to a sub-row of a matrix . . . . .	252
12.9.8	GxB_Row_subassign_Vector: assign to a sub-row of a matrix . .	253
12.9.9	GxB_Vector_subassign_<type>: assign a scalar to a subvector . .	253
12.9.10	GxB_Vector_subassign_Scalar_Vector: assign a scalar to a sub- vector . . . . .	254
12.9.11	GxB_Matrix_subassign_<type>: assign a scalar to a submatrix	254
12.9.12	GxB_Matrix_subassign_Scalar_Vector: assign a scalar to a sub- matrix . . . . .	255
12.10	Duplicate indices in GrB_assign and GxB_subassign . . . . .	257
12.11	Comparing GrB_assign and GxB_subassign . . . . .	260
12.11.1	Example . . . . .	265
12.11.2	Performance of GxB_subassign, GrB_assign and GrB_*_setElement	266
12.12	GrB_apply: apply a unary, binary, or index-unary operator . . . .	269
12.12.1	GrB_Vector_apply: apply a unary operator to a vector . . . . .	269

# 1 Introduction

The GraphBLAS standard defines sparse matrix and vector operations on an extended algebra of semirings. The operations are useful for creating a wide range of graph algorithms.

For example, consider the matrix-matrix multiplication,  $\mathbf{C} = \mathbf{AB}$ . Suppose  $\mathbf{A}$  and  $\mathbf{B}$  are sparse  $n$ -by- $n$  Boolean adjacency matrices of two undirected graphs. If the matrix multiplication is redefined to use logical AND instead of scalar multiply, and if it uses the logical OR instead of add, then the matrix  $\mathbf{C}$  is the sparse Boolean adjacency matrix of a graph that has an edge  $(i, j)$  if node  $i$  in  $\mathbf{A}$  and node  $j$  in  $\mathbf{B}$  share any neighbor in common. The OR-AND pair forms an algebraic semiring, and many graph operations like this one can be succinctly represented by matrix operations with different semirings and different numerical types. GraphBLAS provides a wide range of built-in types and operators, and allows the user application to create new types and operators without needing to recompile the GraphBLAS library.

For more details on SuiteSparse:GraphBLAS, and its use in LAGraph, see [Dav19, Dav23, Dav18, DAK19, ACD<sup>+</sup>20, MDK<sup>+</sup>19].

A full and precise definition of the GraphBLAS specification is provided in *The GraphBLAS C API Specification* by Aydın Buluç, Timothy Mattson, Scott McMillan, José Moreira, Carl Yang, and Benjamin Brock [BMM<sup>+</sup>17a, BMM<sup>+</sup>17b, BBM<sup>+</sup>21], based on *GraphBLAS Mathematics* by Jeremy Kepner [Kep17]. The GraphBLAS C API Specification is available at <http://graphblas.org>. This version of SuiteSparse:GraphBLAS conforms to Version 2.1.0 (Dec 22, 2023) of *The GraphBLAS C API specification*.

In this User Guide, aspects of the GraphBLAS specification that would be true for any GraphBLAS implementation are simply called “GraphBLAS.” Details unique to this particular implementation are referred to as SuiteSparse:GraphBLAS.

All functions, objects, and macros with a name of the form `GxB_*` are SuiteSparse-specific extensions to the specification.

**SPEC:** Non-obvious deviations or additions to the GraphBLAS C API Specification are highlighted in a box like this one, except for `GxB*` methods. They are not highlighted since their name makes it clear that they are extensions to the GraphBLAS C API.

## 2 Basic Concepts

Since the *GraphBLAS C API Specification* provides a precise definition of GraphBLAS, not every detail of every function is provided here. For example, some error codes returned by GraphBLAS are self-explanatory, but since a specification must precisely define all possible error codes a function can return, these are listed in detail in the *GraphBLAS C API Specification*. However, including them here is not essential and the additional information on the page might detract from a clearer view of the essential features of the GraphBLAS functions.

This User Guide also assumes the reader is familiar with MATLAB/Octave. MATLAB supports only the conventional plus-times semiring on sparse double and complex matrices, but a MATLAB-like notation easily extends to the arbitrary semirings used in GraphBLAS. The matrix multiplication in the example in the Introduction can be written in MATLAB notation as `C=A*B`, if the Boolean `OR-AND` semiring is understood. Relying on a MATLAB-like notation allows the description in this User Guide to be expressive, easy to understand, and terse at the same time. *The GraphBLAS C API Specification* also makes use of some MATLAB-like language, such as the colon notation.

MATLAB notation will always appear here in fixed-width font, such as `C=A*B(:,j)`. In standard mathematical notation it would be written as the matrix-vector multiplication  $\mathbf{C} = \mathbf{A}\mathbf{b}_j$  where  $\mathbf{b}_j$  is the  $j$ th column of the matrix  $\mathbf{B}$ . The GraphBLAS standard is a C API and SuiteSparse:GraphBLAS is written in C, and so a great deal of C syntax appears here as well, also in fixed-width font. This User Guide alternates between all three styles as needed.

### 2.1 Graphs and sparse matrices

Graphs can be huge, with many nodes and edges. A dense adjacency matrix  $\mathbf{A}$  for a graph of  $n$  nodes takes  $O(n^2)$  memory, which is impossible if  $n$  is, say, a million. Let  $|\mathbf{A}|$  denote the number of entries in a matrix. Most graphs arising in practice are sparse, however, with only  $|\mathbf{A}| = O(n)$  edges, where  $|\mathbf{A}|$  denotes the number of edges in the graph, or the number of explicit entries present in the data structure for the matrix  $\mathbf{A}$ . Sparse graphs with millions of nodes and edges can easily be created by representing them as sparse matrices, where only explicit values need to be stored. Some graphs

are *hypersparse*, with  $|\mathbf{A}| \ll n$ . SuiteSparse:GraphBLAS supports three kinds of sparse matrix formats: a regular sparse format, taking  $O(n + |\mathbf{A}|)$  space, a hypersparse format taking only  $O(|\mathbf{A}|)$  space, and a bitmap form, taking  $O(n^2)$  space. Full matrices are also represented in  $O(n^2)$  space. Using its hypersparse format, creating a sparse matrix of size  $n$ -by- $n$  where  $n = 2^{60}$  (about  $10^{18}$ ) can be done on quite easily on a commodity laptop, limited only by  $|\mathbf{A}|$ . To the GraphBLAS user application, all matrices look alike, since these formats are opaque, and SuiteSparse:GraphBLAS switches between them at will.

A sparse matrix data structure only stores a subset of the possible  $n^2$  entries, and it assumes the values of entries not stored have some implicit value. In conventional linear algebra, this implicit value is zero, but it differs with different semirings. Explicit values are called *entries* and they appear in the data structure. The *pattern* (also called the *structure*) of a matrix defines where its explicit entries appear. It will be referenced in one of two equivalent ways. It can be viewed as a set of indices  $(i, j)$ , where  $(i, j)$  is in the pattern of a matrix  $\mathbf{A}$  if  $\mathbf{A}(i, j)$  is an explicit value. It can also be viewed as a Boolean matrix  $\mathbf{S}$  where  $\mathbf{S}(i, j)$  is true if  $(i, j)$  is an explicit entry and false otherwise. In MATLAB notation,  $\mathbf{S} = \text{spones}(\mathbf{A})$  or  $\mathbf{S} = (\mathbf{A} \sim 0)$ , if the implicit value is zero. The  $(i, j)$  pairs, and their values, can also be extracted from the matrix via the MATLAB expression  $[\mathbf{I}, \mathbf{J}, \mathbf{X}] = \text{find}(\mathbf{A})$ , where the  $k$ th tuple  $(\mathbf{I}(\mathbf{k}), \mathbf{J}(\mathbf{k}), \mathbf{X}(\mathbf{k}))$  represents the explicit entry  $\mathbf{A}(\mathbf{I}(\mathbf{k}), \mathbf{J}(\mathbf{k}))$ , with numerical value  $\mathbf{X}(\mathbf{k})$  equal to  $a_{ij}$ , with row index  $i = \mathbf{I}(\mathbf{k})$  and column index  $j = \mathbf{J}(\mathbf{k})$ .

The entries in the pattern of  $\mathbf{A}$  can take on any value, including the implicit value, whatever it happens to be. This differs slightly from MATLAB, which always drops all explicit zeros from its sparse matrices. This is a minor difference but GraphBLAS cannot drop explicit zeros. For example, in the max-plus tropical algebra, the implicit value is negative infinity, and zero has a different meaning. Here, the MATLAB notation used will assume that no explicit entries are ever dropped because their explicit value happens to match the implicit value.

*Graph Algorithms in the Language on Linear Algebra*, Kepner and Gilbert, eds., provides a framework for understanding how graph algorithms can be expressed as matrix computations [KG11]. For additional background on sparse matrix algorithms, see also [Dav06] and [DRSL16].

## 2.2 Overview of GraphBLAS methods and operations

GraphBLAS provides a collection of *methods* to create, query, and free its objects: matrices, vectors, scalars, types, operators, monoids, semirings, a descriptor object used for parameter settings, a context object (for controlling parallelism), and a container object (for moving data in and out of GraphBLAS), and an iterator object. Details are given in Section 6. Once these objects are created they can be used in mathematical *operations* (not to be confused with the how the term *operator* is used in GraphBLAS). A short summary of these operations and their nearest MATLAB/Octave analog is given in the table below.

operation	approximate MATLAB/Octave analog
matrix multiplication	$C=A*B$
element-wise operations	$C=A+B$ and $C=A.*B$
reduction to a vector or scalar	$s=\text{sum}(A)$
apply unary operator	$C=-A$
transpose	$C=A'$
submatrix extraction	$C=A(I, J)$
submatrix assignment	$C(I, J)=A$
select	$C=\text{tril}(A)$

GraphBLAS can do far more than what MATLAB/Octave can do in these rough analogs, but the list provides a first step in describing what GraphBLAS can do. Details of each GraphBLAS operation are given in Section 12. With this brief overview, the full scope of GraphBLAS extensions of these operations can now be described.

SuiteSparse:GraphBLAS has 13 built-in scalar types: Boolean, single and double precision floating-point (real and complex), and 8, 16, 32, and 64-bit signed and unsigned integers. In addition, user-defined scalar types can be created from nearly any C `typedef`, as long as the entire type fits in a fixed-size contiguous block of memory (of arbitrary size). All of these types can be used to create GraphBLAS sparse matrices, vectors, or scalars.

The scalar addition of conventional matrix multiplication is replaced with a *monoid*. A monoid is an associative and commutative binary operator  $z=f(x, y)$  where all three domains are the same (the types of  $x$ ,  $y$ , and  $z$ ), and where the operator has an identity value  $id$  such that  $f(x, id)=f(id, x)=x$ . Performing matrix multiplication with a semiring uses a monoid in place of the “add” operator, scalar addition being just one of many possible monoids.

The identity value of addition is zero, since  $x + 0 = 0 + x = x$ . GraphBLAS includes many built-in operators suitable for use as a monoid: `min` (with an identity value of positive infinity), `max` (whose identity is negative infinity), `add` (identity is zero), `multiply` (with an identity of one), four logical operators: `AND`, `OR`, `exclusive-OR`, and `Boolean equality (XNOR)`, four bitwise operators (`AND`, `OR`, `XOR`, and `XNOR`), and the `ANY` operator. See Section 6.3.6 for more details on the unusual `ANY` operator. User-created monoids can be defined with any associative and commutative operator that has an identity value.

Finally, a semiring can use any built-in or user-defined binary operator  $\mathbf{z} = \mathbf{f}(\mathbf{x}, \mathbf{y})$  as its “multiply” operator, as long as the type of its output,  $\mathbf{z}$  matches the type of the semiring’s monoid. The user application can create any semiring based on any types, monoids, and multiply operators, as long these few rules are followed.

Just considering built-in types and operators, GraphBLAS can perform  $\mathbf{C} = \mathbf{A} * \mathbf{B}$  in thousands of unique semirings. With typecasting, any of these semirings can be applied to matrices  $\mathbf{C}$ ,  $\mathbf{A}$ , and  $\mathbf{B}$  of 13 predefined types, in any combination. This results in millions of possible kinds of sparse matrix multiplication supported by GraphBLAS, and this is counting just built-in types and operators. By contrast, MATLAB provides just two semirings for its sparse matrix multiplication  $\mathbf{C} = \mathbf{A} * \mathbf{B}$ : `plus-times-double` and `plus-times-complex`, not counting the typecasting that MATLAB does when multiplying a real matrix times a complex matrix.

A monoid can also be used in a reduction operation, like  $\mathbf{s} = \text{sum}(\mathbf{A})$  in MATLAB. MATLAB provides the `plus`, `times`, `min`, and `max` reductions of a real or complex sparse matrix as  $\mathbf{s} = \text{sum}(\mathbf{A})$ ,  $\mathbf{s} = \text{prod}(\mathbf{A})$ ,  $\mathbf{s} = \text{min}(\mathbf{A})$ , and  $\mathbf{s} = \text{max}(\mathbf{A})$ , respectively. In GraphBLAS, any monoid can be used (`min`, `max`, `plus`, `times`, `AND`, `OR`, `exclusive-OR`, `equality`, `bitwise operators`, or any user-defined monoid on any user-defined type).

Element-wise operations are also expanded from what can be done in MATLAB. Consider matrix addition,  $\mathbf{C} = \mathbf{A} + \mathbf{B}$  in MATLAB. The pattern of the result is the set union of the pattern of  $\mathbf{A}$  and  $\mathbf{B}$ . In GraphBLAS, any binary operator can be used in this set-union “addition.” The operator is applied to entries in the intersection. Entries in  $\mathbf{A}$  but not  $\mathbf{B}$ , or visa-versa, are copied directly into  $\mathbf{C}$ , without any application of the binary operator. The accumulator operation for  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$  described in Section 2.3 is one example of this set-union application of an arbitrary binary operator.

Consider element-wise multiplication,  $\mathbf{C} = \mathbf{A} .* \mathbf{B}$  in MATLAB. The operator

(multiply in this case) is applied to entries in the set intersection, and the pattern of  $C$  just this set intersection. Entries in  $A$  but not  $B$ , or visa-versa, do not appear in  $C$ . In GraphBLAS, any binary operator can be used in this manner, not just scalar multiplication. The difference between element-wise “add” and “multiply” is not the operators, but whether or not the pattern of the result is the set union or the set intersection. In both cases, the operator is only applied to the set intersection.

Finally, GraphBLAS includes a *non-blocking* mode where operations can be left pending, and saved for later. This is very useful for submatrix assignment ( $C(I,J)=A$  where  $I$  and  $J$  are integer vectors), or scalar assignment ( $C(i,j)=x$  where  $i$  and  $j$  are scalar integers). Because of how MATLAB stores its matrices, adding and deleting individual entries is very costly. For example, this is very slow in MATLAB, taking  $O(e^2)$  time (where  $e$  is the number of entries added to the matrix):

```
A = sparse (m,n) ;    % an empty sparse matrix
for k = 1:e
    compute a value x, row index i, and column index j
    A (i,j) = x ;
end
```

The above code is very easy read and simple to write, but exceedingly slow. In MATLAB, the method below is preferred and is far faster, taking at most  $O(e \log e + n)$  time. It can easily be a million times faster than the method above. Unfortunately the second method below is a little harder to read and a little less natural to write:

```
I = zeros (e,1) ;
J = zeros (e,1) ;
X = zeros (e,1) ;
for k = 1:e
    compute a value x, row index i, and column index j
    I (k) = i ;
    J (k) = j ;
    X (k) = x ;
end
A = sparse (I,J,X,m,n) ;
```

GraphBLAS can do both methods. SuiteSparse:GraphBLAS stores its matrices in a format that allows for pending computations, which are done later in bulk, and as a result it can do both methods above equally as fast as the MATLAB `sparse` function, allowing the user to write simpler code.

## 2.3 The accumulator and the mask

Most GraphBLAS operations can be modified via transposing input matrices, using an accumulator operator, applying a mask or its complement, and by clearing all entries the matrix **C** after using it in the accumulator operator but before the final results are written back into it. All of these steps are optional, and are controlled by a descriptor object that holds parameter settings (see Section 6.16) that control the following options:

- the input matrices **A** and/or **B** can be transposed first.
- an accumulator operator can be used, like the plus in the statement  $\mathbf{C} = \mathbf{C} + \mathbf{A} * \mathbf{B}$ . The accumulator operator can be any binary operator, and an element-wise “add” (set union) is performed using the operator.
- an optional *mask* can be used to selectively write the results to the output. The mask is a sparse Boolean matrix **Mask** whose size is the same size as the result. If  $\mathbf{Mask}(i, j)$  is true, then the corresponding entry in the output can be modified by the computation. If  $\mathbf{Mask}(i, j)$  is false, then the corresponding in the output is protected and cannot be modified by the computation. The **Mask** matrix acts exactly like logical matrix indexing in MATLAB, with one minor difference: in GraphBLAS notation, the mask operation is  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$ , where the mask **M** appears only on the left-hand side. In MATLAB, it would appear on both sides as  $\mathbf{C}(\mathbf{Mask}) = \mathbf{Z}(\mathbf{Mask})$ . If no mask is provided, the **Mask** matrix is implicitly all true. This is indicated by passing the value **GrB\_NULL** in place of the **Mask** argument in GraphBLAS operations.

This process can be described in mathematical notation as:

$$\begin{aligned} \mathbf{A} &= \mathbf{A}^T, \text{ if requested via descriptor (first input option)} \\ \mathbf{B} &= \mathbf{B}^T, \text{ if requested via descriptor (second input option)} \\ \mathbf{T} &\text{ is computed according to the specific operation} \\ \mathbf{C}\langle\mathbf{M}\rangle &= \mathbf{C} \odot \mathbf{T}, \text{ accumulating and writing the results back via the mask} \end{aligned}$$

The application of the mask and the accumulator operator is written as  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$  where  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$  denotes the application of the accumulator operator, and  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$  denotes the mask operator via the Boolean matrix **M**. The Accumulator Phase,  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$ , is performed as follows:

**Accumulator Phase:** compute  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$ :

```

    if accum is NULL
         $\mathbf{Z} = \mathbf{T}$ 
    else
         $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$ 

```

The accumulator operator is  $\odot$  in GraphBLAS notation, or `accum` in the code. The pattern of  $\mathbf{C} \odot \mathbf{T}$  is the set union of the patterns of  $\mathbf{C}$  and  $\mathbf{T}$ , and the operator is applied only on the set intersection of  $\mathbf{C}$  and  $\mathbf{T}$ . Entries in neither the pattern of  $\mathbf{C}$  nor  $\mathbf{T}$  do not appear in the pattern of  $\mathbf{Z}$ . That is:

```

    for all entries  $(i, j)$  in  $\mathbf{C} \cap \mathbf{T}$  (that is, entries in both  $\mathbf{C}$  and  $\mathbf{T}$ )
         $z_{ij} = c_{ij} \odot t_{ij}$ 
    for all entries  $(i, j)$  in  $\mathbf{C} \setminus \mathbf{T}$  (that is, entries in  $\mathbf{C}$  but not  $\mathbf{T}$ )
         $z_{ij} = c_{ij}$ 
    for all entries  $(i, j)$  in  $\mathbf{T} \setminus \mathbf{C}$  (that is, entries in  $\mathbf{T}$  but not  $\mathbf{C}$ )
         $z_{ij} = t_{ij}$ 

```

The Accumulator Phase is followed by the Mask/Replace Phase,  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$  as controlled by the `GrB_REPLACE` and `GrB_COMP` descriptor options:

**Mask/Replace Phase:** compute  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$ :

```

    if (GrB_REPLACE) delete all entries in  $\mathbf{C}$ 
    if Mask is NULL
        if (GrB_COMP)
             $\mathbf{C}$  is not modified
        else
             $\mathbf{C} = \mathbf{Z}$ 
    else
        if (GrB_COMP)
             $\mathbf{C}\langle\neg\mathbf{M}\rangle = \mathbf{Z}$ 
        else
             $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$ 

```

Both phases of the accum/mask process are illustrated in MATLAB notation in Figure 1.

A GraphBLAS operation starts with its primary computation, producing a result  $\mathbf{T}$ ; for matrix multiply,  $\mathbf{T}=\mathbf{A}*\mathbf{B}$ , or if  $\mathbf{A}$  is transposed first,  $\mathbf{T}=\mathbf{A}'*\mathbf{B}$ , for example. Applying the accumulator, mask (or its complement) to obtain the final result matrix  $\mathbf{C}$  can be expressed in the MATLAB `accum_mask` function

```

function C = accum_mask (C, Mask, accum, T, C_replace, Mask_complement)
[m n] = size (C.matrix) ;
Z.matrix = zeros (m, n) ;
Z.pattern = false (m, n) ;

if (isempty (accum))
    Z = T ;      % no accum operator
else
    % Z = accum (C,T), like Z=C+T but with an binary operator, accum
    p = C.pattern & T.pattern ; Z.matrix (p) = accum (C.matrix (p), T.matrix (p));
    p = C.pattern & ~T.pattern ; Z.matrix (p) = C.matrix (p) ;
    p = ~C.pattern & T.pattern ; Z.matrix (p) = T.matrix (p) ;
    Z.pattern = C.pattern | T.pattern ;
end

% apply the mask to the values and pattern
C.matrix = mask (C.matrix, Mask, Z.matrix, C_replace, Mask_complement) ;
C.pattern = mask (C.pattern, Mask, Z.pattern, C_replace, Mask_complement) ;
end

function C = mask (C, Mask, Z, C_replace, Mask_complement)
% replace C if requested
if (C_replace)
    C (:,:) = 0 ;
end
if (isempty (Mask))          % if empty, Mask is implicit ones(m,n)
    % implicitly, Mask = ones (size (C))
    if (~Mask_complement)
        C = Z ;              % this is the default
    else
        C = C ;              % Z need never have been computed
    end
else
    % apply the mask
    if (~Mask_complement)
        C (Mask) = Z (Mask) ;
    else
        C (~Mask) = Z (~Mask) ;
    end
end
end
end

```

Figure 1: Applying the mask and accumulator,  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$

shown in the figure. This function is an exact, fully functional, and nearly-complete description of the GraphBLAS accumulator/mask operation. The only aspects it does not consider are typecasting (see Section 2.4), and the value of the implicit identity (for those, see another version in the `Test` folder).

One aspect of GraphBLAS cannot be as easily expressed in a MATLAB sparse matrix: namely, what is the implicit value of entries not in the pattern? To accommodate this difference in the `accum_mask` MATLAB function, each sparse matrix `A` is represented with its values `A.matrix` and its pattern, `A.pattern`. The latter could be expressed as the sparse matrix `A.pattern=spones(A)` or `A.pattern=(A~=0)` in MATLAB, if the implicit value is zero. With different semirings, entries not in the pattern can be 1, `+Inf`, `-Inf`, or whatever is the identity value of the monoid. As a result, Figure 1 performs its computations on two MATLAB matrices: the values in `A.matrix` and the pattern in the logical matrix `A.pattern`. Implicit values are untouched.

The final computation in Figure 1 with a complemented `Mask` is easily expressed in MATLAB as `C(~Mask)=Z(~Mask)` but this is costly if `Mask` is very sparse (the typical case). It can be computed much faster in MATLAB without complementing the sparse `Mask` via:

$$R = Z ; R (Mask) = C (Mask) ; C = R ;$$

A set of MATLAB functions that precisely compute the  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$  operation according to the full GraphBLAS specification is provided in SuiteSparse:GraphBLAS as `GB_spec_accum.m`, which computes  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$ , and `GB_spec_mask.m`, which computes  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$ . SuiteSparse:GraphBLAS includes a complete list of `GB_spec_*` functions that illustrate every GraphBLAS operation.

The methods in Figure 1 rely heavily on MATLAB’s logical matrix indexing. For those unfamiliar with logical indexing in MATLAB, here is short summary. Logical matrix indexing in MATLAB is written as `A(Mask)` where `A` is any matrix and `Mask` is a logical matrix the same size as `A`. The expression `x=A(Mask)` produces a column vector `x` consisting of the entries of `A` where `Mask` is true. On the left-hand side, logical submatrix assignment `A(Mask)=x` does the opposite, copying the components of the vector `x` into the places in `A` where `Mask` is true. For example, to negate all values greater than 10 using logical indexing in MATLAB:

```

>> A = magic (4)
A =
    16     2     3    13
     5    11    10     8
     9     7     6    12
     4    14    15     1
>> A (A>10) = - A (A>10)
A =
   -16     2     3   -13
     5   -11    10     8
     9     7     6   -12
     4   -14   -15     1

```

In MATLAB, logical indexing with a sparse matrix **A** and sparse logical matrix **Mask** is a built-in method. The Mask operator in GraphBLAS works identically as sparse logical indexing in MATLAB, but is typically far faster in SuiteSparse:GraphBLAS than the same operation using MATLAB sparse matrices.

## 2.4 Typecasting

If an operator  $\mathbf{z}=\mathbf{f}(\mathbf{x})$  or  $\mathbf{z}=\mathbf{f}(\mathbf{x},\mathbf{y})$  is used with inputs that do not match its inputs **x** or **y**, or if its result **z** does not match the type of the matrix it is being stored into, then the values are typecasted. Typecasting in GraphBLAS extends beyond just operators. Almost all GraphBLAS methods and operations are able to typecast their results, as needed.

If one type can be typecasted into the other, they are said to be *compatible*. All built-in types are compatible with each other. GraphBLAS cannot typecast user-defined types thus any user-defined type is only compatible with itself. When GraphBLAS requires inputs of a specific type, or when one type cannot be typecast to another, the GraphBLAS function returns an error code, **GrB\_DOMAIN\_MISMATCH** (refer to Section 5.6 for a complete list of error codes). Typecasting can only be done between built-in types, and it follows the rules of the ANSI C language (not MATLAB) wherever the rules of ANSI C are well-defined.

However, unlike MATLAB, the C11 language specification states that the results of typecasting a **float** or **double** to an integer type is not always defined. In SuiteSparse:GraphBLAS, whenever C leaves the result undefined the rules used in MATLAB are followed. In particular **+Inf** converts to the largest integer value, **-Inf** converts to the smallest (zero for unsigned in-

tegers), and `NaN` converts to zero. Positive values outside the range of the integer are converted to the largest positive integer, and negative values less than the most negative integer are converted to that most negative integer. Other than these special cases, SuiteSparse:GraphBLAS trusts the C compiler for the rest of its typecasting.

Typecasting to `bool` is fully defined in the C language specification, even for `NaN`. The result is `false` if the value compares equal to zero, and true otherwise. Thus `NaN` converts to `true`. This is unlike MATLAB, which does not allow a typecast of a `NaN` to the MATLAB logical type.

**SPEC:** the GraphBLAS API C Specification states that typecasting follows the rules of ANSI C. Yet C leaves some typecasting undefined. All typecasting between built-in types in SuiteSparse:GraphBLAS is precisely defined, as an extension to the specification.

**SPEC:** Some functions do not make use of all of their inputs; in particular the binary operators `FIRST`, `SECOND`, and `ONEB`, and many of the index unary operators. The Specification requires that the inputs to these operators must be compatible with (that is, can be typecasted to) the inputs to the operators, even if those inputs are not used and no typecasting would ever occur. As an extension to the specification, SuiteSparse:GraphBLAS does not perform this error check on unused inputs of built-in operators. For example, the `GrB_FIRST_INT64` operator can be used in `GrB_eWiseMult(C, ..., A, B, ...)` on a matrix B of any type, including user-defined types. For this case, the matrix A must be compatible with `GrB_INT64`.

## 2.5 Notation and list of GraphBLAS operations

As a summary of what GraphBLAS can do, the following table lists all GraphBLAS operations. Upper case letters denote a matrix, lower case letters are vectors, and **AB** denote the multiplication of two matrices over a semiring.

Each operation takes an optional `GrB_Descriptor` argument that modifies the operation. The input matrices **A** and **B** can be optionally transposed, the mask **M** can be complemented, and **C** can be cleared of its entries after it is used in  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$  but before the  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$  assignment. Vectors are never transposed via the descriptor.

Let  $\mathbf{A} \oplus \mathbf{B}$  denote the element-wise operator that produces a set union pattern (like  $\mathbf{A}+\mathbf{B}$  in MATLAB). Any binary operator can be used this way in GraphBLAS, not just plus. Let  $\mathbf{A} \otimes \mathbf{B}$  denote the element-wise operator that produces a set intersection pattern (like  $\mathbf{A}.*\mathbf{B}$  in MATLAB); any binary operator can be used this way, not just times.

Reduction of a matrix  $\mathbf{A}$  to a vector reduces the  $i$ th row of  $\mathbf{A}$  to a scalar  $w_i$ . This is like  $\mathbf{w}=\text{sum}(\mathbf{A}')$  since by default, MATLAB reduces down the columns, not across the rows.

GrB_mxm	matrix-matrix multiply	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}\mathbf{B}$
GrB_vxm	vector-matrix multiply	$\mathbf{w}^\top\langle\mathbf{m}^\top\rangle = \mathbf{w}^\top \odot \mathbf{u}^\top \mathbf{A}$
GrB_mxv	matrix-vector multiply	$\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{A}\mathbf{u}$
GrB_eWiseMult	element-wise, set intersection	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot (\mathbf{A} \otimes \mathbf{B})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot (\mathbf{u} \otimes \mathbf{v})$
GrB_eWiseAdd	element-wise, set union	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot (\mathbf{A} \oplus \mathbf{B})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot (\mathbf{u} \oplus \mathbf{v})$
GxB_eWiseUnion	element-wise, set union	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot (\mathbf{A} \oplus \mathbf{B})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot (\mathbf{u} \oplus \mathbf{v})$
GrB_extract	extract submatrix	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}(\mathbf{I}, \mathbf{J})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{u}(\mathbf{i})$
GxB_subassign	assign submatrix (with submask for $\mathbf{C}(\mathbf{I}, \mathbf{J})$ )	$\mathbf{C}(\mathbf{I}, \mathbf{J})\langle\mathbf{M}\rangle = \mathbf{C}(\mathbf{I}, \mathbf{J}) \odot \mathbf{A}$ $\mathbf{w}(\mathbf{i})\langle\mathbf{m}\rangle = \mathbf{w}(\mathbf{i}) \odot \mathbf{u}$
GrB_assign	assign submatrix (with mask for $\mathbf{C}$ )	$\mathbf{C}\langle\mathbf{M}\rangle(\mathbf{I}, \mathbf{J}) = \mathbf{C}(\mathbf{I}, \mathbf{J}) \odot \mathbf{A}$ $\mathbf{w}\langle\mathbf{m}\rangle(\mathbf{i}) = \mathbf{w}(\mathbf{i}) \odot \mathbf{u}$
GrB_apply	apply unary operator	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(\mathbf{A})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(\mathbf{u})$
	apply binary operator	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(\mathbf{A}, y)$ $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(x, \mathbf{A})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(\mathbf{u}, y)$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(x, \mathbf{u})$
	apply index-unary op	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(\mathbf{A}, i, j, k)$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(\mathbf{u}, i, 0, k)$
GrB_select	select entries	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \text{select}(\mathbf{A}, i, j, k)$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \text{select}(\mathbf{u}, i, 0, k)$
GrB_reduce	reduce to vector reduce to scalar	$\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot [\oplus_j \mathbf{A}(:, j)]$ $s = s \odot [\oplus_{ij} \mathbf{A}(i, j)]$
GrB_transpose	transpose	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}^\top$
GrB_kronecker	Kronecker product	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \text{kron}(\mathbf{A}, \mathbf{B})$

### 3 Changes in GraphBLAS v10: 32/64 bit integers

GraphBLAS v10 adds a new feature that improves performance and reduces memory requirements for GraphBLAS matrices and vectors: the use of any mix of 32-bit and 64-bit integers in the internal data structures for the `GrB_Matrix`, `GrB_Vector`, and `GrB_Scalar` (the latter is nominally revised, but only because SuiteSparse:GraphBLAS stores its `GrB_Scalar` as a 1-by-1 matrix).

All prior methods work without any modification to the user application, so v10 is upward-compatible with prior versions of GraphBLAS.

#### 3.1 Controlling the sizes of integers

Different integers are used for different parts of the matrix/vector data structure. The decision as to which integers to use is determined by the dimensions and number of entries in the matrix. The decisions can also be modified by `GrB_set` and queried by `GrB_get`. A matrix can have up to three different kinds of integers. If a matrix is  $m$ -by- $n$  with  $e$  entries, with default settings:

- if  $m > 2^{31}$ : 64-bit integers must be used for the row indices of a matrix; otherwise, 32-bit integers may be used.
- if  $n > 2^{31}$ : 64-bit integers must be used for the column indices of a matrix; otherwise, 32-bit integers may be used.
- if  $e > 2^{32}$ : 64-bit integers must be used for the row/column offsets of a matrix; otherwise 32-bit integers may be used.

See Section [10.13](#) for details.

#### 3.2 Passing arrays to/from GraphBLAS

Several of the methods in the GraphBLAS v2.1 C API use plain C arrays of type `uint64_t` to pass lists of integers to GraphBLAS. These are extended to allow any integers arrays to be passed, by adding new methods where all plain C arrays (including pointers to numerical values for `build` and `extractTuples`) are replaced with `GrB_Vectors`. The new methods are given

a name that matches the method they revised, with a `_Vector` appended on the end. All of the new methods are accessible via the polymorphic interface, using the existing polymorphic name. In the methods below, all `I`, `J`, and `X` parameters become `GrB_Vector` objects.

- `GrB_Vector_build`: build a vector from  $(I, X)$  or  $(I, \text{scalar})$  tuples.
  - `GxB_Vector_build_Vector` (`w`, `I`, `X`, `dup`, `desc`)  
(see Section 6.9.8).
  - `GxB_Vector_build_Scalar_Vector` (`w`, `I`, `scalar`, `desc`)  
(see Section 6.9.10).
- `GrB_Matrix_build`: build a matrix from  $(I, J, X)$  or  $(I, J, \text{scalar})$  tuples.
  - `GxB_Matrix_build_Vector` (`C`, `I`, `J`, `X`, `dup`, `desc`)  
(see Section 6.10.9).
  - `GxB_Matrix_build_Scalar_Vector` (`C`, `I`, `J`, `scalar`, `desc`)  
(see Section 6.10.11).
- `GrB_Vector_extractTuples`: extract  $(I, X)$  tuples from a vector.
  - `GxB_Vector_extractTuples_Vector` (`I`, `X`, `v`, `desc`)  
(see Section 6.9.16).
- `GrB_Matrix_extractTuples`: extract  $(I, J, X)$  tuples from a matrix.
  - `GxB_Matrix_extractTuples_Vector` (`I`, `J`, `X`, `A`, `desc`)  
(see Section 6.10.17).
- `GrB_assign`:  $C\langle M \rangle(I, J) = C(I, J) \odot A$ 
  - `GxB_Vector_assign_Vector` (`w`, `mask`, `accum`, `u`, `I`, `desc`)  
(see Section 12.8.2).
  - `GxB_Matrix_assign_Vector` (`C`, `Mask`, `accum`, `A`, `I`, `J`, `desc`)  
(see Section 12.8.4).
  - `GxB_Col_assign_Vector` (`C`, `mask`, `accum`, `u`, `I`, `j`, `desc`)  
(see Section 12.8.6).

- `GxB_Row_assign_Vector` (`C`, `mask`, `accum`, `u`, `i`, `J`, `desc`)  
(see Section 12.8.8).
- `GxB_Vector_assign_Scalar_Vector` (`w`, `mask`, `accum`, `scalar`, `I`, `desc`)  
(see Section 12.8.10).
- `GxB_Matrix_assign_Scalar_Vector` (`C`, `Mask`, `accum`, `scalar`, `I`, `J`, `desc`)  
(see Section 12.8.12).
- **GrB\_subassign:**  $C(I, J)\langle M \rangle = C(I, J) \odot A$ 
  - `GxB_Vector_subassign_Vector` (`w`, `mask`, `accum`, `u`, `I`, `desc`)  
(see Section 12.9.2).
  - `GxB_Matrix_subassign_Vector` (`C`, `Mask`, `accum`, `A`, `I`, `J`, `desc`)  
(see Section 12.9.4).
  - `GxB_Col_subassign_Vector` (`C`, `mask`, `accum`, `u`, `I`, `j`, `desc`)  
(see Section 12.9.6).
  - `GxB_Row_subassign_Vector` (`C`, `mask`, `accum`, `u`, `i`, `J`, `desc`)  
(see Section 12.9.8).
  - `GxB_Vector_subassign_Scalar_Vector` (`w`, `mask`, `accum`, `scalar`, `I`, `desc`)  
(see Section 12.9.10).
  - `GxB_Matrix_subassign_Scalar_Vector` (`C`, `Mask`, `accum`, `scalar`, `I`, `J`, `desc`)  
(see Section 12.9.12).
- **GrB\_extract:**  $C\langle M \rangle = C \odot A(I, J)$ 
  - `GxB_Vector_extract_Vector` (`w`, `mask`, `accum`, `u`, `I`, `desc`)  
(see Section 12.7.2).
  - `GxB_Matrix_extract_Vector` (`C`, `Mask`, `accum`, `A`, `I`, `J`, `desc`)  
(see Section 12.7.4).
  - `GxB_Col_extract_Vector` (`w`, `mask`, `accum`, `A`, `I`, `j`, `desc`)  
(see Section 12.7.6).

In each of the above methods where `I`, `J`, and `X` are `GrB_Vector` inputs to the method (all but `extractTuples`), the vectors can be interpreted in up to 3 different ways. For the first two ways, suppose `extractTuples` is used to extract two lists from a vector `I`, `J`, or `X`: values and indices. Then either

of those two lists can then be used by the method. The default is to use the values, but the indices can be selected by changing the following descriptor fields:

- `GxB_ROWINDEX_LIST`: how the `GrB_Vector I` is interpreted.
- `GxB_COLINDEX_LIST`: how the `GrB_Vector J` is interpreted.
- `GxB_VALUE_LIST`: how `GrB_Vector X` is interpreted (for `GrB_build` only).

These can be set to one of the following values:

- `GrB_DEFAULT` or `GxB_USE_VALUES`: use the values of the vector (default).
- `GxB_USE_INDICES`: use the indices of the vector.
- `GxB_IS_STRIDE`: use the values, of size 3, for a strided range, or `lo:inc:hi` in MATLAB notation. This usage is limited to the `I` and `J` vectors (except this option may not be used for `GrB_build`). The vector must have exactly three entries, `lo`, `hi`, and `inc`, in that order.

### 3.3 Container methods: loading/unloading data to/from a matrix or vector

The new methods described in the previous Section 3.2 provide `GrB_Vector` inputs and outputs. This section gives an overview of how data is moved between these opaque objects and user-visible C arrays, using the new `load/unload` methods.

See Section 6.12 for all of the details of the new load/unload methods, using a new *Container* object.

Methods in the v2.1 GraphBLAS C Specification can be used, but these methods require a copy (`GrB*_build`, `GrB*_extractTuples`, `GrB*_import` and `GrB*_export`). The following two methods accomplish this task when the vectors are dense, with all possible entries present.

- `GxB_Vector_load`: this method moves data in  $O(1)$  time from a user-visible C array into a `GrB_Vector`. The vector length and type are revised to match the new data from the C array. Ownership is normally

transferred to the `GrB_Vector`, but this can be revised with a `handling` parameter. The C array is passed in as a `void *` pointer, and its type is indicated by a `GrB_Type` parameter. See Section 6.12.1 for details.

- `GxB_Vector_unload`: this method moves data in  $O(1)$  time from a `GrB_Vector` into a user-visible C array (assuming the vector has no pending work; if so, that work is done first). The length of the `GrB_Vector` is reduced to zero, to denote that it no longer holds any content. The vector must be dense; it must have the same number of entries as its size (that is `GrB_Vector_nvals` and `GrB_Vector_size` must return the same value). The C array is returned as a `void *` pointer, and its type is indicated by a `GrB_Type` parameter. See Section 6.12.2 for details.

To move data between a `GrB_Matrix` or `GrB_Vector` in all other cases, a new `GxB_Container` object is introduced. This object is non-opaque but contains opaque objects. Its primary components are five dense `GrB_Vectors` that hold the contents of the matrix/vector. The data in these dense vectors can then be loaded/unloaded via `GxB_Vector_load` and `GxB_Vector_unload`.

The following methods operate on the `Container` object:

- `GxB_Container_new`: creates a container. (see Section 6.12.3).
- `GxB_Container_free`: frees a container. (see Section 6.12.4).
- `GxB_load_Matrix_from_Container`: moves all of the data from a `GxB_Container` into a `GrB_Matrix` in  $O(1)$  time. (see Section 6.12.5).
- `GxB_load_Vector_from_Container`: moves all of the data from a `GxB_Container` into a `GrB_Vector` in  $O(1)$  time. (see Section 6.12.6).
- `GxB_unload_Matrix_into_Container`: moves all of the data from a `GrB_Matrix` into a `GxB_Container` in  $O(1)$  time. (see Section 6.12.7).
- `GxB_unload_Vector_into_Container`: moves all of the data from a `GrB_Vector` into a `GxB_Container` in  $O(1)$  time. (see Section 6.12.8).

### 3.4 Historical methods: pack/unpack

GraphBLAS v5.1.0 (released in June 2021) added a suite of `GxB_pack` and `GxB_unpack` methods to move data between opaque objects (`GrB_Matrix` and

`GrB_Vector`) and user-visible C arrays, in  $O(1)$  time unless the data format needed to be revised.

These methods are now declared *historical*, which means they will be kept in working order but will no longer be documented. Refer to the GraphBLAS v9.4.5 User Guide for documentaion for the pack/unpack methods.

In GraphBLAS v10, these methods still pack/unpack their contents into `uint64_t` \* user arrays. If the matrix has 32-bit integers, this requires a copy and typecast. Thus, performance will be degraded for existing user codes that expect  $O(1)$  time to pack/unpack their matrices/vectors.

Extending the pack/unpack to handle arbitrary C integer arrays would lead to an explosion in the number of methods in the API, and it would get worse if other integers are added (16-bit and 128-bit for example). Rather than extend pack/unpack to handle a wide range of integer types, new methods using the `GxB_Container` are introduced instead (see Section 3.3), to rapidly move data into/out of a `GrB_Matrix` or `GrB_Vector` in  $O(1)$  time and space.

## 4 Interfaces to MATLAB, Octave, Python, Julia, Go, Java, ...

The MATLAB/Octave interface to SuiteSparse:GraphBLAS is included with this distribution, described in Section 4.1. Python, Julia, Go, and Java interfaces are available. These are not part of the SuiteSparse:GraphBLAS distribution. See the links below.

### 4.1 MATLAB/Octave Interface

An easy-to-use MATLAB/Octave interface for SuiteSparse:GraphBLAS is available; see the documentation in the `GraphBLAS/GraphBLAS` folder for details. Start with the `README.md` file in that directory. An easy-to-read output of the MATLAB demos can be found in `GraphBLAS/GraphBLAS/demo/html`.

The MATLAB/Octave interface adds the `@GrB` class, which is an opaque MATLAB/Octave object that contains a GraphBLAS matrix, either double or single precision (real or complex), boolean, or any of the built-in integer types. MATLAB/Octave sparse and full matrices can be arbitrarily mixed with GraphBLAS matrices. The following overloaded operators and methods all work as you would expect for any matrix. The matrix multiplication `A*B` uses the conventional `PLUS_TIMES` semiring.

<code>A+B</code>	<code>A-B</code>	<code>A*B</code>	<code>A.*B</code>	<code>A./B</code>	<code>A.\B</code>	<code>A.^b</code>	<code>A/b</code>	<code>C=A(I,J)</code>
<code>-A</code>	<code>+A</code>	<code>~A</code>	<code>A'</code>	<code>A.'</code>	<code>A&amp;B</code>	<code>A B</code>	<code>b\A</code>	<code>C(I,J)=A</code>
<code>A~=B</code>	<code>A&gt;B</code>	<code>A==B</code>	<code>A&lt;=B</code>	<code>A&gt;=B</code>	<code>A&lt;B</code>	<code>[A,B]</code>	<code>[A;B]</code>	<code>A(1:end,1:end)</code>

For a list of overloaded operations and static methods, type `methods GrB` in MATLAB/Octave, or `help GrB` for more details.

**Limitations:** Some features for MATLAB/Octave sparse matrices are not yet available for GraphBLAS matrices. Some of these may be added in future releases.

- `GrB` matrices with dimension larger than  $2^{53}$  do not display properly in the `whos` command. The size is displayed correctly with `disp` or `display`.
- Non-blocking mode is not exploited.
- Linear indexing: `A(:)` for a 2D matrix, and `I=find(A)`.
- Singleton expansion.

- Dynamically growing arrays, where  $C(i)=x$  can increase the size of  $C$ .
- Saturating element-wise binary and unary operators for integers. For  $C=A+B$  with MATLAB `uint8` matrices, results saturate if they exceed 255. This is not compatible with a monoid for  $C=A*B$ , and thus MATLAB does not support matrix-matrix multiplication with `uint8` matrices. In GraphBLAS, `uint8` addition acts in a modulo fashion.
- Solvers, so that  $x=A\backslash b$  could return a GF(2) solution, for example.
- Sparse matrices with dimension higher than 2.

## 4.2 Performance of MATLAB versus GraphBLAS

MATLAB R2021a uses SuiteSparse:GraphBLAS as a built-in library, but uses it only for  $C=A*B$  when both  $A$  and  $B$  are sparse. In prior versions of MATLAB,  $C=A*B$  relied on the `SFMULT` and `SSMULT` packages in SuiteSparse, which are single-threaded (also written by this author). The GraphBLAS `GrB_mxm` is up to 30x faster on a 20-core Intel Xeon, compared with  $C=A*B$  in MATLAB R2020b and earlier. With MATLAB R2021a and later, the performance of  $C=A*B$  when using MATLAB sparse matrices is identical to the performance for GraphBLAS matrices, since the same code is being used by both (`GrB_mxm`).

Other methods in GraphBLAS are also faster, some *extremely* so, but are not yet exploited as built-in operations MATLAB. In particular, the statement  $C(M)=A$  (where  $M$  is a logical matrix) takes under a second for a large sparse problem when using GraphBLAS via its `@GrB` interface. By stark contrast, MATLAB would take about 4 or 5 days, a speedup of about 500,000x. For a smaller problem, GraphBLAS takes 0.4 seconds while MATLAB takes 28 hours (a speedup of about 250,000x). Both cases use the same statement with the same syntax ( $C(M)=A$ ) and compute exactly the same result. Below are the results for  $n$ -by- $n$  matrices in GraphBLAS v5.0.6 and MATLAB R2020a, on a Dell XPS13 laptop (16GB RAM, Intel(R) Core(TM) i7-8565U CPU @ 1.80GHz with 4 hardware cores). GraphBLAS is using 4 threads.

n	nnz(C)	nnz(M)	GraphBLAS (sec)	MATLAB (sec)	speedup
2,048	20,432	2,048	0.005	0.024	4.7
4,096	40,908	4,096	0.003	0.115	39
8,192	81,876	8,191	0.009	0.594	68
16,384	163,789	16,384	0.009	2.53	273
32,768	327,633	32,767	0.014	12.4	864
65,536	655,309	65,536	0.025	65.9	2,617
131,072	1,310,677	131,070	0.055	276.2	4,986
262,144	2,621,396	262,142	0.071	1,077	15,172
524,288	5,242,830	524,288	0.114	5,855	51,274
1,048,576	10,485,713	1,048,576	0.197	27,196	137,776
2,097,152	20,971,475	2,097,152	0.406	100,799	248,200
4,194,304	41,942,995	4,194,304	0.855	4 to 5 days?	500,000?

The assignment  $C(I, J)=A$  in MATLAB, when using `@GrB` objects, is up to 1000x faster than the same statement with the same syntax, when using MATLAB sparse matrices instead. Matrix concatenation  $C = [A \ B]$  is about 17 times faster in GraphBLAS, on a 20-core Intel Xeon. For more details, see the `GraphBLAS/GraphBLAS/demo` folder and its contents.

Below is a comparison of other methods in SuiteSparse:GraphBLAS, compared with MATLAB 2021a. SuiteSparse:GraphBLAS: v6.1.4 (Jan 12, 2022), was used, compiled with gcc 11.2.0. The system is an Intel(R) Xeon(R) CPU E5-2698 v4 @ 2.20GHz (20 hardware cores, 40 threads), Ubuntu 20.04, 256GB RAM. Full details appear in the `GraphBLAS/GraphBLAS/demo/benchmark` folder. For this matrix, SuiteSparse:GraphBLAS is anywhere from 3x to 17x faster than the built-in methods in MATLAB. This matrix is not special, but is typical of the relative performance of many large matrices. Note that two of these ( $C=L*S$  and  $C=S*R$ ) rely on an older version of SuiteSparse:GraphBLAS (v3.3.3) built into MATLAB R2021a.

Legend:

S: large input sparse matrix (n-by-n), the GAP-twitter matrix  
x: dense vector (1-by-n or n-by-1)  
F: dense matrix (4-by-n or n-by-4)

### 4.3 Python Interface

See Michel Pelletier's Python interface at <https://github.com/michelp/pygraphblas>; it also appears at <https://anaconda.org/conda-forge/pygraphblas>.

See Jim Kitchen and Erik Welch's (both from Anaconda, Inc.) Python interface at <https://github.com/python-graphblas/python-graphblas> (formerly known as grblas). See also <https://anaconda.org/conda-forge/graphblas>.

### 4.4 Julia Interface

The Julia interface is at <https://github.com/JuliaSparse/SuiteSparseGraphBLAS.jl>, developed by Will Kimmerer, Abhinav Mehndiratta, Miha Zgubic, and Viral Shah. Unlike the MATLAB/Octave interface (and like the Python interfaces) the Julia interface can keep pending work (zombies, pending tuples, jumbled state) in a `GrB_Matrix`. This makes Python and Julia the best high-level interfaces for SuiteSparse:GraphBLAS. MATLAB is not as well suited, since it does not allow inputs to a function or mexFunction to be modified, so any pending work must be finished before a matrix can be used as input.

### 4.5 Go Interface

Pascal Costanza (Intel) has a Go interface to GraphBLAS and LAGraph:

- forGraphBLASGo: <https://github.com/intel/forGraphBLASGo>, which is almost a complete wrapper for SuiteSparse:GraphBLAS. Documentation is at <https://pkg.go.dev/github.com/intel/forGraphBLASGo>.
- forLAGraphGo: <https://github.com/intel/forLAGraphGo>, which is in progress. Documentation is at <https://pkg.go.dev/github.com/intel/forLAGraphGo>.

### 4.6 Java Interface

Fabian Murariu is working on a Java interface. See <https://github.com/fabianmurariu/graphblas-java-native>.

## 5 GraphBLAS Initialization/Finalization

A user application that directly relies on GraphBLAS must include the `GraphBLAS.h` header file:

```
#include "GraphBLAS.h"
```

The `GraphBLAS.h` file defines functions, types, and macros prefixed with `GrB_` and `GxB_` that may be used in user applications. The prefix `GrB_` denotes items that appear in the official *GraphBLAS C API Specification*. The prefix `GxB_` refers to SuiteSparse-specific extensions to the GraphBLAS API.

The `GraphBLAS.h` file includes all the definitions required to use GraphBLAS, including the following macros that can assist a user application in compiling and using GraphBLAS.

There are two version numbers associated with SuiteSparse:GraphBLAS: the version of the *GraphBLAS C API Specification* it conforms to, and the version of the implementation itself. These can be used in the following manner in a user application:

```
#if GxB_SPEC_VERSION >= GxB_VERSION (2,0,3)
... use features in GraphBLAS specification 2.0.3 ...
#else
... only use features in early specifications
#endif

#if GxB_IMPLEMENTATION >= GxB_VERSION (5,2,0)
... use features from version 5.2.0 (or later)
of a specific GraphBLAS implementation
#endif
```

SuiteSparse:GraphBLAS also defines the following strings with `#define`. Refer to the `GraphBLAS.h` file for details.

Macro	purpose
<code>GxB_IMPLEMENTATION_ABOUT</code>	this particular implementation, copyright, and URL
<code>GxB_IMPLEMENTATION_DATE</code>	the date of this implementation
<code>GxB_SPEC_ABOUT</code>	the GraphBLAS specification for this implementation
<code>GxB_SPEC_DATE</code>	the date of the GraphBLAS specification
<code>GxB_IMPLEMENTATION_LICENSE</code>	the license for this particular implementation

Finally, SuiteSparse:GraphBLAS gives itself a unique name of the form `GxB_SUITESPARSE_GRAPHBLAS` that the user application can use in `#ifdef` tests. This is helpful in case a particular implementation provides non-standard features that extend the GraphBLAS specification, such as additional predefined built-in operators, or if a GraphBLAS implementation does not yet fully implement all of the GraphBLAS specification.

For example, SuiteSparse:GraphBLAS predefines additional built-in operators not in the specification. If the user application wishes to use these in any GraphBLAS implementation, an `#ifdef` can control when they are used. Refer to the examples in the `GraphBLAS/Demo` folder.

As another example, the GraphBLAS API states that an implementation need not define the order in which `GrB_Matrix_build` assembles duplicate tuples in its `[I,J,X]` input arrays. As a result, no particular ordering should be relied upon in general. However, SuiteSparse:GraphBLAS does guarantee an ordering, and this guarantee will be kept in future versions of SuiteSparse:GraphBLAS as well. Since not all implementations will ensure a particular ordering, the following can be used to exploit the ordering returned by SuiteSparse:GraphBLAS.

```
#ifdef GxB_SUITESPARSE_GRAPHBLAS
// duplicates in I, J, X assembled in a specific order;
// results are well-defined even if op is not associative.
GrB_Matrix_build (C, I, J, X, nvals, op) ;
#else
// duplicates in I, J, X assembled in no particular order;
// results are undefined if op is not associative.
GrB_Matrix_build (C, I, J, X, nvals, op) ;
#endif
```

The remainder of this section describes GraphBLAS functions that start or finalize GraphBLAS, error handling, and the GraphBLAS integer.

GraphBLAS function/type	purpose	Section
<code>GrB_Index</code>	the GraphBLAS integer	<a href="#">5.1</a>
<code>GrB_init</code>	start up GraphBLAS	<a href="#">5.2</a>
<code>GrB_getVersion</code>	C API supported by the library	<a href="#">5.3</a>
<code>GxB_init</code>	start up GraphBLAS with different <code>malloc</code>	<a href="#">5.4</a>
<code>GrB_Info</code>	status code returned by GraphBLAS functions	<a href="#">5.5</a>
<code>GrB_error</code>	get more details on the last error	<a href="#">5.6</a>
<code>GrB_finalize</code>	finish GraphBLAS	<a href="#">5.7</a>

## 5.1 GrB\_Index: the GraphBLAS integer

Matrix and vector dimensions and indexing rely on a specific integer, `GrB_Index`, which is defined in `GraphBLAS.h` as

```
typedef uint64_t GrB_Index ;
```

Row and column indices of an `nrows`-by-`ncols` matrix range from zero to the `nrows-1` for the rows, and zero to `ncols-1` for the columns. Indices are zero-based, like C, and not one-based, like MATLAB/Octave. In SuiteSparse:GraphBLAS, the largest permitted index value is `GrB_INDEX_MAX`, defined as  $2^{60} - 1$ . The largest permitted matrix or vector dimension is  $2^{60}$  (that is, `GrB_INDEX_MAX+1`). The largest `GrB_Matrix` that SuiteSparse:GraphBLAS can construct is thus  $2^{60}$ -by- $2^{60}$ . An  $n$ -by- $n$  matrix **A** that size can easily be constructed in practice with  $O(|\mathbf{A}|)$  memory requirements, where  $|\mathbf{A}|$  denotes the number of entries that explicitly appear in the pattern of **A**. The time and memory required to construct a matrix that large does not depend on  $n$ , since SuiteSparse:GraphBLAS can represent **A** in hypersparse form (see Section 10.10.2). The largest `GrB_Vector` that can be constructed is  $2^{60}$ -by-1.

Internally, GraphBLAS may store its integer indices using 32-bit integers (as of GraphBLAS v10.0.0). See Section 10.13 for details.

## 5.2 GrB\_init: initialize GraphBLAS

```
typedef enum
{
    GrB_NONBLOCKING = 0,    // methods may return with pending computations
    GrB_BLOCKING = 1       // no computations are ever left pending
}
GrB_Mode ;
```

```
GrB_Info GrB_init          // start up GraphBLAS
(
    int mode                // blocking or non-blocking mode (GrB_Mode)
) ;
```

`GrB_init` must be called before any other GraphBLAS operation. It defines the mode that GraphBLAS will use: blocking or non-blocking. With

blocking mode, all operations finish before returning to the user application. With non-blocking mode, operations can be left pending, and are computed only when needed. Non-blocking mode can be much faster than blocking mode, by many orders of magnitude in extreme cases. Blocking mode should be used only when debugging a user application. The mode cannot be changed once it is set by `GrB_init`.

GraphBLAS objects are opaque. This allows GraphBLAS to postpone operations and then do them later in a more efficient manner by rearranging them and grouping them together. In non-blocking mode, the computations required to construct an opaque GraphBLAS object might not be finished when the GraphBLAS method or operation returns to the user. However, user-provided arrays are not opaque, and GraphBLAS methods and operations that read them (such as `GrB_Matrix_build`) or write to them (such as `GrB_Matrix_extractTuples`) always finish reading them, or creating them, when the method or operation returns to the user application.

All methods and operations that extract values from a GraphBLAS object and return them into non-opaque user arrays always ensure that the user-visible arrays are fully populated when they return: `GrB*_reduce` (to scalar), `GrB*_nvals`, `GrB*_extractElement`, and `GrB*_extractTuples`. These functions do *not* guarantee that the opaque objects they depend on are finalized. To do that, use `GrB_wait` instead.

SuiteSparse:GraphBLAS is multithreaded internally, via OpenMP, and it is also safe to use in a multithreaded user application. See Section 18 for details. User threads must not operate on the same matrices at the same time, with one exception. Multiple user threads can use the same matrices or vectors as inputs to GraphBLAS operations or methods, but only if they have no pending operations (use `GrB_wait` first). User threads cannot simultaneously modify a matrix or vector via any GraphBLAS operation or method.

It is safe to use the internal parallelism in SuiteSparse:GraphBLAS on matrices, vectors, and scalars that are not yet completed. The library handles this on its own. The `GrB_wait` function is only needed when a user application makes multiple calls to GraphBLAS in parallel, from multiple user threads.

With multiple user threads, exactly one user thread must call `GrB_init` before any user thread may call any `GrB_*` or `GxB_*` function. When the user application is finished, exactly one user thread must call `GrB_finalize`, after which no user thread may call any `GrB_*` or `GxB_*` function. The mode

of a GraphBLAS session can be queried with `GrB_get`; see Section 10 for details.

### 5.3 `GrB_getVersion`: determine the C API Version

```
GrB_Info GrB_getVersion          // run-time access to C API version number
(
    unsigned int *version,        // returns GRB_VERSION
    unsigned int *subversion      // returns GRB_SUBVERSION
) ;
```

GraphBLAS defines two compile-time constants that define the version of the C API Specification that is implemented by the library: `GRB_VERSION` and `GRB_SUBVERSION`. If the user program was compiled with one version of the library but linked with a different one later on, the compile-time version check with `GRB_VERSION` would be stale. `GrB_getVersion` thus provides a run-time access of the version of the C API Specification supported by the library.

### 5.4 `GxB_init`: initialize with alternate malloc

```
GrB_Info GxB_init                // start up GraphBLAS and also define malloc
(
    int mode,                    // blocking or non-blocking mode (GrB_Mode)
    // pointers to memory management functions.
    void * (* user_malloc_func ) (size_t),
    void * (* user_calloc_func ) (size_t, size_t),
    void * (* user_realloc_func ) (void *, size_t),
    void (* user_free_func ) (void *)
) ;
```

`GxB_init` is identical to `GrB_init`, except that it also redefines the memory management functions that SuiteSparse:GraphBLAS will use. Giving the user application control over this is particularly important when using the `GxB_*serialize` and `GxB_Container` methods described in Section 6.11 and 6.12, since they require the user application and GraphBLAS to use the same memory manager. `user_calloc_func` and `user_realloc_func` are optional, and may be `NULL`. If `NULL`, then the `user_malloc_func` is relied on instead, for all memory allocations. These functions can only be set once, when GraphBLAS starts. They can be queried using `GrB_get` (see

Section 10.2). Either `GrB_init` or `GxB_init` must be called before any other GraphBLAS operation, but not both. The functions passed to `GxB_init` must be thread-safe. The following usage is identical to `GrB_init(mode)`:

```
GxB_init (mode, malloc, calloc, realloc, free) ;
```

## 5.5 GrB\_Info: status code returned by GraphBLAS

Each GraphBLAS method and operation returns its status to the caller as its return value, an enumerated type (an `enum`) called `GrB_Info`. The first two values in the following table denote a successful status, the rest are error codes.

Error	value	description
<code>GrB_SUCCESS</code>	0	the method or operation was successful
<code>GrB_NO_VALUE</code>	1	the method was successful, but the entry does not appear in the matrix or vector.
<code>GxB_EXHAUSTED</code>	2	the iterator is exhausted
<code>GrB_UNINITIALIZED_OBJECT</code>	-1	object has not been initialized
<code>GrB_NULL_POINTER</code>	-2	input pointer is NULL
<code>GrB_INVALID_VALUE</code>	-3	generic error code; some value is bad
<code>GrB_INVALID_INDEX</code>	-4	a row or column index is out of bounds
<code>GrB_DOMAIN_MISMATCH</code>	-5	object domains are not compatible
<code>GrB_DIMENSION_MISMATCH</code>	-6	matrix dimensions do not match
<code>GrB_OUTPUT_NOT_EMPTY</code>	-7	output matrix already has values in it
<code>GrB_NOT_IMPLEMENTED</code>	-8	not implemented in SS:GrB
<code>GrB_ALREADY_SET</code>	-9	field already written to
<code>GrB_PANIC</code>	-101	unrecoverable error
<code>GrB_OUT_OF_MEMORY</code>	-102	out of memory
<code>GrB_INSUFFICIENT_SPACE</code>	-103	output array not large enough
<code>GrB_INVALID_OBJECT</code>	-104	object is corrupted
<code>GrB_INDEX_OUT_OF_BOUNDS</code>	-105	a row or column index is out of bounds
<code>GrB_EMPTY_OBJECT</code>	-106	a input scalar has no entry
<code>GxB_JIT_ERROR</code>	-7001	JIT compiler error
<code>GxB_OUTPUT_IS_READONLY</code>	-7003	output has read-only components

Not all GraphBLAS methods or operations can return all status codes. In the discussions of each method and operation in this User Guide, most of the obvious error code returns are not discussed. For example, if a required

input is a NULL pointer, then `GrB_NULL_POINTER` is returned. Only error codes specific to the method or that require elaboration are discussed here. For a full list of the status codes that each GraphBLAS function can return, refer to *The GraphBLAS C API Specification* [BMM<sup>+</sup>17b, BBM<sup>+</sup>21].

## 5.6 GrB\_error: get more details on the last error

```
GrB_Info GrB_error      // return a string describing the last error
(
    const char **error, // error string
    <type> object      // a GrB_matrix, GrB_Vector, etc.
) ;
```

Each GraphBLAS method and operation returns a `GrB_Info` error code. The `GrB_error` function returns additional information on the error for a particular object in a null-terminated string. The string returned by `GrB_error` is never a NULL string, but it may have length zero (with the first entry being the `'\0'` string-termination value). The string must not be freed or modified.

```
info = GrB_some_method_here (C, ...) ;
if (! (info == GrB_SUCCESS || info == GrB_NO_VALUE))
{
    char *err ;
    GrB_error (&err, C) ;
    printf ("info: %d error: %s\n", info, err) ;
}
```

If the matrix `C` has no error status, or if the error is not recorded in the string, an empty non-null string is returned. In particular, out-of-memory conditions result in an empty string from `GrB_error`.

SuiteSparse:GraphBLAS reports many helpful details via `GrB_error`. For example, if a row or column index is out of bounds, the report will state what those bounds are. If a matrix dimension is incorrect, the mismatching dimensions will be provided. Refer to the output of the example programs in the `Demo` and `Test` folder, which intentionally generate errors to illustrate the use of `GrB_error`.

The only functions in GraphBLAS that return an error string are functions that have a single input/output argument `C`, as a `GrB_Matrix`, `GrB_Vector`, `GrB_Scalar`, or `GrB_Descriptor`. Methods that create these objects (such as `GrB_Matrix_new`) return a NULL object on failure, so these methods cannot also return an error string in their output argument.

Any subsequent GraphBLAS method that modifies the object `C` clears the error string.

Note that `GrB_NO_VALUE` is an not error, but an informational status. `GrB*_extractElement(&x,A,i,j)`, which does `x=A(i,j)`, returns this value to indicate that `A(i,j)` is not present in the matrix. That method does not have an input/output object so it cannot return an error string.

## 5.7 GrB\_finalize: finish GraphBLAS

```
GrB_Info GrB_finalize ( ) ;    // finish GraphBLAS
```

`GrB_finalize` must be called as the last GraphBLAS operation, even after all calls to `GrB_free`. All GraphBLAS objects created by the user application should be freed first, before calling `GrB_finalize` since `GrB_finalize` will not free those objects. In non-blocking mode, GraphBLAS may leave some computations as pending. These computations can be safely abandoned if the user application frees all GraphBLAS objects it has created and then calls `GrB_finalize`. When the user application is finished, exactly one user thread must call `GrB_finalize`.

## 6 GraphBLAS Objects and their Methods

SuiteSparse:GraphBLAS defines 14 different objects to represent matrices, vectors, scalars, data types, operators (binary, unary, and index-unary), monoids, semirings, a *descriptor* object used to specify optional parameters that modify the behavior of a GraphBLAS operation, a *context* object for controlling computational resources, a matrix/vector iterator, and a container object for moving data in and out of the GraphBLAS opaque matrix/vector objects.

The GraphBLAS API makes a distinction between *methods* and *operations*. A method is a function that works on a GraphBLAS object, creating it, destroying it, or querying its contents. An operation (not to be confused with an operator) acts on matrices and/or vectors in a semiring.

---

GrB_Type	a scalar data type
GrB_UnaryOp	a unary operator $z = f(x)$ , where $z$ and $x$ are scalars
GrB_BinaryOp	a binary operator $z = f(x, y)$ , where $z$ , $x$ , and $y$ are scalars
GrB_IndexUnaryOp	an index-unary operator
GxB_IndexBinaryOp	an index-binary operator
GrB_Monoid	an associative and commutative binary operator and its identity value
GrB_Semiring	a monoid that defines the “plus” and a binary operator that defines the “multiply” for an algebraic semiring
GrB_Matrix	a 2D sparse matrix of any type
GrB_Vector	a 1D sparse column vector of any type
GrB_Scalar	a scalar of any type
GrB_Descriptor	a collection of parameters that modify an operation
GxB_Context	allocating computational resources
GxB_Iterator	a matrix/vector iterator (See Section 14)
GxB_Container	for moving data between GraphBLAS and a user application

---

Most of these objects are implemented in C as an opaque handle, which is a pointer to a data structure held by GraphBLAS. User applications may not examine the content of the object directly; instead, they can pass the handle back to GraphBLAS which will do the work. Assigning one handle to another is valid but it does not make a copy of the underlying object.

The `GxB_Container` object is non-opaque but includes opaque objects as its contents. All other objects are entirely opaque.

## 6.1 The GraphBLAS type: GrB\_Type

A GraphBLAS **GrB\_Type** defines the type of scalar values that a matrix or vector contains, and the type of scalar operands for a unary or binary operator. There are 13 built-in types, and a user application can define any types of its own as well. The built-in types correspond to built-in types in C (in the `#include` files `stdbool.h`, `stdint.h`, and `complex.h`) as listed in the following table.

GraphBLAS type	C type	description	range
GrB_BOOL	<code>bool</code>	Boolean	true (1), false (0)
GrB_INT8	<code>int8_t</code>	8-bit signed integer	-128 to 127
GrB_INT16	<code>int16_t</code>	16-bit integer	$-2^{15}$ to $2^{15} - 1$
GrB_INT32	<code>int32_t</code>	32-bit integer	$-2^{31}$ to $2^{31} - 1$
GrB_INT64	<code>int64_t</code>	64-bit integer	$-2^{63}$ to $2^{63} - 1$
GrB_UINT8	<code>uint8_t</code>	8-bit unsigned integer	0 to 255
GrB_UINT16	<code>uint16_t</code>	16-bit unsigned integer	0 to $2^{16} - 1$
GrB_UINT32	<code>uint32_t</code>	32-bit unsigned integer	0 to $2^{32} - 1$
GrB_UINT64	<code>uint64_t</code>	64-bit unsigned integer	0 to $2^{64} - 1$
GrB_FP32	<code>float</code>	32-bit IEEE 754	-Inf to +Inf
GrB_FP64	<code>double</code>	64-bit IEEE 754	-Inf to +Inf
GxB_FC32	<code>float complex</code>	32-bit complex	-Inf to +Inf
GxB_FC64	<code>double complex</code>	64-bit complex	-Inf to +Inf

The C11 definitions of `float complex` and `double complex` are not always available. The `GraphBLAS.h` header defines them as `GxB_FC32_t` and `GxB_FC64_t`, respectively.

The user application can also define new types based on any `typedef` in the C language whose values are held in a contiguous region of memory of fixed size. For example, a user-defined **GrB\_Type** could be created to hold any C `struct` whose content is self-contained. A C `struct` containing pointers might be problematic because GraphBLAS would not know to dereference the pointers to traverse the entire “scalar” entry, but this can be done if the objects referenced by these pointers are not moved. A user-defined complex type with real and imaginary types can be defined, or even a “scalar” type containing a fixed-sized dense matrix (see Section 6.1.1). The possibilities are endless. GraphBLAS can create and operate on sparse matrices and vectors in any of these types, including any user-defined ones. For user-defined types, GraphBLAS simply moves the data around itself (via `memcpy`), and then

passes the values back to user-defined functions when it needs to do any computations on the type. The next sections describe the methods for the `GrB_Type` object:

GraphBLAS function	purpose	Section
<code>GrB_Type_new</code>	create a user-defined type	<a href="#">6.1.1</a>
<code>GxB_Type_new</code>	create a user-defined type, with name and definition	<a href="#">6.1.2</a>
<code>GrB_Type_wait</code>	wait for a user-defined type	<a href="#">6.1.3</a>
<code>GxB_Type_from_name</code>	return the type from its name	<a href="#">6.1.4</a>
<code>GrB_Type_free</code>	free a user-defined type	<a href="#">6.1.5</a>
<code>GrB_get</code>	get properties of a type	<a href="#">10.3</a>
<code>GrB_set</code>	set the type name/definition	<a href="#">10.3</a>

### 6.1.1 `GrB_Type_new`: create a user-defined type

```
GrB_Info GrB_Type_new          // create a new GraphBLAS type
(
    GrB_Type *type,            // handle of user type to create
    size_t sizeof_ctype        // size = sizeof (ctype) of the C type
) ;
```

`GrB_Type_new` creates a new user-defined type. The `type` is a handle, or a pointer to an opaque object. The handle itself must not be `NULL` on input, but the content of the handle can be undefined. On output, the handle contains a pointer to a newly created type. The `ctype` is the type in C that will be used to construct the new GraphBLAS type. It can be either a built-in C type, or defined by a `typedef`. The second parameter should be passed as `sizeof(ctype)`. The only requirement on the C type is that `sizeof(ctype)` is valid in C, and that the type reside in a contiguous block of memory so that it can be moved with `memcpy`. For example, to create a user-defined type called `Complex` for double-precision complex values using the C11 `double complex` type, the following can be used. A complete example can be found in the `usercomplex.c` and `usercomplex.h` files in the `Demo` folder.

```
#include <math.h>
#include <complex.h>
GrB_Type Complex ;
GrB_Type_new (&Complex, sizeof (double complex)) ;
```

To demonstrate the flexibility of the `GrB_Type`, consider a “scalar” consisting of 4-by-4 floating-point matrix and a string. This type might be useful

for the 4-by-4 translation/rotation/scaling matrices that arise in computer graphics, along with a string containing a description or even a regular expression that can be parsed and executed in a user-defined operator. All that is required is a fixed-size type, where `sizeof(ctype)` is a constant.

```
typedef struct
{
    float stuff [4][4] ;
    char whatstuff [64] ;
}
wildtype ;
GrB_Type WildType ;
GrB_Type_new (&WildType, sizeof (wildtype)) ;
```

With this type a sparse matrix can be created in which each entry consists of a 4-by-4 dense matrix `stuff` and a 64-character string `whatstuff`. GraphBLAS treats this 4-by-4 as a “scalar.” Any GraphBLAS method or operation that simply moves data can be used with this type without any further information from the user application. For example, entries of this type can be assigned to and extracted from a matrix or vector, and matrices containing this type can be transposed. A working example (`wildtype.c` in the `Demo` folder) creates matrices and multiplies them with a user-defined semiring with this type.

Performing arithmetic on matrices and vectors with user-defined types requires operators to be defined. Refer to Section 17.5 for more details on these example user-defined types.

User defined types created by `GrB_Type_new` will not work with the JIT; use `GxB_Type_new` instead.

### 6.1.2 GxB\_Type\_new: create a user-defined type (with name and definition)

```
GrB_Info GxB_Type_new          // create a new named GraphBLAS type
(
    GrB_Type *type,             // handle of user type to create
    size_t sizeof_ctype,        // size = sizeof (ctype) of the C type
    const char *type_name,      // name of the type (max 128 characters)
    const char *type_defn       // typedef for the type (no max length)
) ;
```

`GxB_Type_new` creates a type with a name and definition that are known to GraphBLAS, as strings. The `type_name` is any valid string (max length of

128 characters, including the required null-terminating character) that may appear as the name of a C type created by a C `typedef` statement. It must not contain any white-space characters. For example, to create a type of size  $16*4+1 = 65$  bytes, with a 4-by-4 dense float array and a 32-bit integer:

```
typedef struct { float x [4][4] ; int color ; } myquaternion ;
GrB_Type MyQtype ;
GxB_Type_new (&MyQtype, sizeof (myquaternion), "myquaternion",
    "typedef struct { float x [4][4] ; int color ; } myquaternion ;") ;
```

The `type_name` and `type_defn` are both null-terminated strings. The two strings are optional, but are required to enable the JIT compilation of kernels that use this type. At most `GxB_MAX_NAME_LEN` (128) characters are accessed in `type_name`; characters beyond that limit are silently ignored.

If the `sizeof_ctype` is zero, and the strings are valid, a JIT kernel is compiled just to determine the size of the type. This is feature useful for interfaces in languages other than C, which could create valid strings for C types but would not have a reliable way to determine the size of the type.

The above example is identical to the following usage, except that `GrB_Type_new` requires `sizeof_ctype` to be nonzero, and equal to the size of the C type.

```
typedef struct { float x [4][4] ; int color ; } myquaternion ;
GrB_Type MyQtype ;
GxB_Type_new (&MyQtype, sizeof (myquaternion)) ;
GrB_set (MyQtype, "myquaternion", GxB_JIT_C_NAME) ;
GrB_set (MyQtype, "typedef struct { float x [4][4] ; int color ; } myquaternion ;"
    GxB_JIT_C_DEFINITION) ;
```

### 6.1.3 GrB\_Type\_wait: wait for a type

```
GrB_Info GrB_wait                // wait for a user-defined type
(
    GrB_Type type,                // type to wait for
    int mode                      // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

After creating a user-defined type, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing except to ensure that `type` is valid.

#### 6.1.4 GrB\_Type\_from\_name: return the type from its name

```
GrB_Info GrB_Type_from_name      // return the built-in GrB_Type from a name
(
    GrB_Type *type,              // built-in type, or NULL if user-defined
    const char *type_name        // array of size at least GrB_MAX_NAME_LEN
);
```

Returns the built-in type from the corresponding name of the type. The following examples both return `type` as `GrB_BOOL`.

```
GrB_Type_from_name (&type, "bool") ;
GrB_Type_from_name (&type, "GrB_BOOL") ;
```

If the name is from a user-defined type, the `type` is returned as `NULL`. This is not an error condition. The user application must itself do this translation since GraphBLAS does not keep a registry of all user-defined types.

With this function, a user application can manage the translation for both built-in types and its own user-defined types, as in the following example.

```
typedef struct { double x ; char stuff [16] ; } myfirsttype ;
typedef struct { float z [4][4] ; int color ; } myquaternion ;
GrB_Type MyType1, MyQType ;
GrB_Type_new (&MyType1, sizeof (myfirsttype), "myfirsttype",
    "typedef struct { double x ; char stuff [16] ; } myfirsttype ;") ;
GrB_Type_new (&MyQType, sizeof (myquaternion), "myquaternion",
    "typedef struct { float z [4][4] ; int color ; } myquaternion ;") ;

GrB_Matrix A ;
// ... create a matrix A of some built-in or user-defined type

// later on, to query the type of A:
size_t typesize ;
GrB_Scalar_new (s, GrB_UINT64) ;
GrB_get (type, s, GrB_SIZE) ;
GrB_Scalar_extractElement (&typesize, GrB_UINT64) ;
GrB_Type atype ;
char atype_name [GrB_MAX_NAME_LEN] ;
GrB_get (A, atype_name, GrB_EL_TYPE_STRING) ;
GrB_Type_from_name (&atype, atype_name) ;
if (atype == NULL)
{
    // This is not yet an error. It means that A has a user-defined type.
    if ((strcmp (atype_name, "myfirsttype")) == 0) atype = MyType1 ;
}
```

```

        else if ((strcmp (atype_name, "myquaternion")) == 0) atype = MyQType ;
        else { ... this is now an error ... the type of A is unknown. }
    }

```

### 6.1.5 GrB\_Type\_free: free a user-defined type

```

GrB_Info GrB_free                // free a user-defined type
(
    GrB_Type *type                // handle of user-defined type to free
) ;

```

GrB\_Type\_free frees a user-defined type. Either usage:

```

GrB_Type_free (&type) ;
GrB_free (&type) ;

```

frees the user-defined `type` and sets `type` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `type == NULL` on input.

It is safe to attempt to free a built-in type. SuiteSparse:GraphBLAS silently ignores the request and returns `GrB_SUCCESS`. A user-defined type should not be freed until all operations using the type are completed. SuiteSparse:GraphBLAS attempts to detect this condition but it must query a freed object in its attempt. This is hazardous and not recommended. Operations on such objects whose type has been freed leads to undefined behavior.

It is safe to first free a type, and then a matrix of that type, but after the type is freed the matrix can no longer be used. The only safe thing that can be done with such a matrix is to free it.

The function signature of `GrB_Type_free` uses the generic name `GrB_free`, which can free any GraphBLAS object. See Section 6.17 details. GraphBLAS includes many such generic functions. When describing a specific variation, a function is described with its specific name in this User Guide (such as `GrB_Type_free`). When discussing features applicable to all specific forms, the generic name is used instead (such as `GrB_free`).

## 6.2 GraphBLAS unary operators: $\text{GrB\_UnaryOp}$ , $z = f(x)$

A unary operator is a scalar function of the form  $z = f(x)$ . The domain (type) of  $z$  and  $x$  need not be the same.

In the notation in the tables below,  $T$  is any of the 13 built-in types and is a place-holder for `BOOL`, `INT8`, `UINT8`, ... `FP32`, `FP64`, `FC32`, or `FC64`. For example, `GrB_AINV_INT32` is a unary operator that computes  $\mathbf{z} = -\mathbf{x}$  for two values  $\mathbf{x}$  and  $\mathbf{z}$  of type `GrB_INT32`.

The notation  $R$  refers to any real type (all but `FC32` and `FC64`),  $I$  refers to any integer type (`INT*` and `UINT*`),  $F$  refers to any real or complex floating point type (`FP32`, `FP64`, `FC32`, or `FC64`),  $Z$  refers to any complex floating point type (`FC32` or `FC64`), and  $N$  refers to `INT32` or `INT64`.

The logical negation operator `GrB_LNOT` only works on Boolean types. The `GxB_LNOT_R` functions operate on inputs of type  $R$ , implicitly typecasting their input to Boolean and returning result of type  $R$ , with a value 1 for true and 0 for false. The operators `GxB_LNOT_BOOL` and `GrB_LNOT` are identical.

Unary operators for all types			
GraphBLAS name	types (domains)	$z = f(x)$	description
<code>GxB_ONE_T</code>	$T \rightarrow T$	$z = 1$	one
<code>GrB_IDENTITY_T</code>	$T \rightarrow T$	$z = x$	identity
<code>GrB_AINV_T</code>	$T \rightarrow T$	$z = -x$	additive inverse
<code>GrB_MINV_T</code>	$T \rightarrow T$	$z = 1/x$	multiplicative inverse

Unary operators for real and integer types			
GraphBLAS name	types (domains)	$z = f(x)$	description
<code>GrB_ABS_T</code>	$R \rightarrow R$	$z =  x $	absolute value
<code>GrB_LNOT</code>	<code>bool</code> $\rightarrow$ <code>bool</code>	$z = \neg x$	logical negation
<code>GxB_LNOT_R</code>	$R \rightarrow R$	$z = \neg(x \neq 0)$	logical negation
<code>GrB_BNOT_I</code>	$I \rightarrow I$	$z = \neg x$	bitwise negation

Index-based unary operators for any type (including user-defined)			
GraphBLAS name	types (domains)	$z = f(a_{ij})$	description
<code>GxB_POSITIONI_N</code>	$\rightarrow N$	$z = i$	row index (0-based)
<code>GxB_POSITIONI1_N</code>	$\rightarrow N$	$z = i + 1$	row index (1-based)
<code>GxB_POSITIONJ_N</code>	$\rightarrow N$	$z = j$	column index (0-based)
<code>GxB_POSITIONJ1_N</code>	$\rightarrow N$	$z = j + 1$	column index (1-based)

Unary operators for floating-point types (real and complex)			
GraphBLAS name	types (domains)	$z = f(x)$	description
GxB_SQRT_ $F$	$F \rightarrow F$	$z = \sqrt{x}$	square root
GxB_LOG_ $F$	$F \rightarrow F$	$z = \log_e(x)$	natural logarithm
GxB_EXP_ $F$	$F \rightarrow F$	$z = e^x$	natural exponent
GxB_LOG10_ $F$	$F \rightarrow F$	$z = \log_{10}(x)$	base-10 logarithm
GxB_LOG2_ $F$	$F \rightarrow F$	$z = \log_2(x)$	base-2 logarithm
GxB_EXP2_ $F$	$F \rightarrow F$	$z = 2^x$	base-2 exponent
GxB_EXPM1_ $F$	$F \rightarrow F$	$z = e^x - 1$	natural exponent - 1
GxB_LOG1P_ $F$	$F \rightarrow F$	$z = \log(x + 1)$	natural log of $x + 1$
GxB_SIN_ $F$	$F \rightarrow F$	$z = \sin(x)$	sine
GxB_COS_ $F$	$F \rightarrow F$	$z = \cos(x)$	cosine
GxB_TAN_ $F$	$F \rightarrow F$	$z = \tan(x)$	tangent
GxB_ASIN_ $F$	$F \rightarrow F$	$z = \sin^{-1}(x)$	inverse sine
GxB_ACOS_ $F$	$F \rightarrow F$	$z = \cos^{-1}(x)$	inverse cosine
GxB_ATAN_ $F$	$F \rightarrow F$	$z = \tan^{-1}(x)$	inverse tangent
GxB_SINH_ $F$	$F \rightarrow F$	$z = \sinh(x)$	hyperbolic sine
GxB_COSH_ $F$	$F \rightarrow F$	$z = \cosh(x)$	hyperbolic cosine
GxB_TANH_ $F$	$F \rightarrow F$	$z = \tanh(x)$	hyperbolic tangent
GxB_ASINH_ $F$	$F \rightarrow F$	$z = \sinh^{-1}(x)$	inverse hyperbolic sine
GxB_ACOSH_ $F$	$F \rightarrow F$	$z = \cosh^{-1}(x)$	inverse hyperbolic cosine
GxB_ATANH_ $F$	$F \rightarrow F$	$z = \tanh^{-1}(x)$	inverse hyperbolic tangent
GxB_SIGNUM_ $F$	$F \rightarrow F$	$z = \operatorname{sgn}(x)$	sign, or signum function
GxB_CEIL_ $F$	$F \rightarrow F$	$z = \lceil x \rceil$	ceiling function
GxB_FLOOR_ $F$	$F \rightarrow F$	$z = \lfloor x \rfloor$	floor function
GxB_ROUND_ $F$	$F \rightarrow F$	$z = \operatorname{round}(x)$	round to nearest
GxB_TRUNC_ $F$	$F \rightarrow F$	$z = \operatorname{trunc}(x)$	round towards zero
GxB_ISINF_ $F$	$F \rightarrow \text{bool}$	$z = \operatorname{isinf}(x)$	true if $\pm\infty$
GxB_ISNAN_ $F$	$F \rightarrow \text{bool}$	$z = \operatorname{isnan}(x)$	true if NaN
GxB_ISFINITE_ $F$	$F \rightarrow \text{bool}$	$z = \operatorname{isfinite}(x)$	true if finite

Unary operators for floating-point types (real only)			
GraphBLAS name	types (domains)	$z = f(x)$	description
GxB_LGAMMA_ $R$	$R \rightarrow R$	$z = \log( \Gamma(x) )$	log of gamma function
GxB_TGAMMA_ $R$	$R \rightarrow R$	$z = \Gamma(x)$	gamma function
GxB_ERF_ $R$	$R \rightarrow R$	$z = \operatorname{erf}(x)$	error function
GxB_ERFC_ $R$	$R \rightarrow R$	$z = \operatorname{erfc}(x)$	complimentary error function
GxB_CBRT_ $R$	$R \rightarrow R$	$z = x^{1/3}$	cube root
GxB_FREXPX_ $R$	$R \rightarrow R$	$z = \operatorname{freexp}(x)$	normalized fraction
GxB_FREXPE_ $R$	$R \rightarrow R$	$z = \operatorname{frexpe}(x)$	normalized exponent

Unary operators for complex types			
GraphBLAS name	types (domains)	$z = f(x)$	description
GxB_CONJ_Z	$Z \rightarrow Z$	$z = \bar{x}$	complex conjugate
GxB_ABS_Z	$Z \rightarrow F$	$z =  x $	absolute value
GxB_CREAL_Z	$Z \rightarrow F$	$z = \text{real}(x)$	real part
GxB_CIMAG_Z	$Z \rightarrow F$	$z = \text{imag}(x)$	imaginary part
GxB_CARG_Z	$Z \rightarrow F$	$z = \text{carg}(x)$	angle

Built-in index-based unary operators return the row or column index of an entry. For a matrix  $z = f(a_{ij})$  returns  $z = i$  or  $z = j$ , or  $+1$  for 1-based indices. The latter is useful in the MATLAB/Octave interface, where row and column indices are 1-based. When applied to a vector,  $j$  is always zero, and  $i$  is the index in the vector. These built-in unary operators come in two types: INT32 and INT64, which is the type of the output,  $z$ . The functions are agnostic to the type of their inputs; they only depend on the position of the entries, not their values. User-defined index-based operators cannot be defined by `GrB_UnaryOp_new`; use `GrB_IndexUnaryOp_new` instead; see Section 6.4.

`GxB_FREXPX` and `GxB_FREXPE` return the mantissa and exponent, respectively, from the C11 `frexp` function. The exponent is returned as a floating-point value, not an integer.

The operators `GxB_EXPM1_FC*` and `GxB_LOG1P_FC*` for complex types are currently not accurate. They will be revised in a future version.

The functions `casin`, `casinf`, `casinh`, and `casinhf` provided by Microsoft Visual Studio for computing  $\sin^{-1}(x)$  and  $\sinh^{-1}(x)$  when  $x$  is complex do not compute the correct result. Thus, the unary operators `GxB_ASIN_FC32`, `GxB_ASIN_FC64`, `GxB_ASINH_FC32`, and `GxB_ASINH_FC64` do not work properly if the MS Visual Studio compiler is used. These functions work properly if the gcc, icc, or clang compilers are used on Linux or MacOS.

Integer division by zero normally terminates an application, but this is avoided in SuiteSparse:GraphBLAS. For details, see the binary `GrB_DIV_T` operators.

**SPEC:** The definition of integer division by zero is an extension to the specification.

The next sections define the following methods for the `GrB_UnaryOp` object:

GraphBLAS function	purpose	Section
<code>GrB_UnaryOp_new</code>	create a user-defined unary operator	<a href="#">6.2.1</a>
<code>GxB_UnaryOp_new</code>	create a named user-defined unary operator	<a href="#">6.2.2</a>
<code>GrB_UnaryOp_wait</code>	wait for a user-defined unary operator	<a href="#">6.2.3</a>
<code>GrB_UnaryOp_free</code>	free a user-defined unary operator	<a href="#">6.2.4</a>
<code>GrB_get</code>	get properties of an operator	<a href="#">10.4</a>
<code>GrB_set</code>	set the operator name/definition	<a href="#">10.4</a>

### 6.2.1 `GrB_UnaryOp_new`: create a user-defined unary operator

```

GrB_Info GrB_UnaryOp_new          // create a new user-defined unary operator
(
    GrB_UnaryOp *unaryop,          // handle for the new unary operator
    void *function,                // pointer to the unary function
    GrB_Type ztype,                // type of output z
    GrB_Type xtype                 // type of input x
) ;

```

`GrB_UnaryOp_new` creates a new unary operator. The new operator is returned in the `unaryop` handle, which must not be `NULL` on input. On output, its contents contains a pointer to the new unary operator.

The two types `xtype` and `ztype` are the GraphBLAS types of the input  $x$  and output  $z$  of the user-defined function  $z = f(x)$ . These types may be built-in types or user-defined types, in any combination. The two types need not be the same, but they must be previously defined before passing them to `GrB_UnaryOp_new`.

The `function` argument to `GrB_UnaryOp_new` is a pointer to a user-defined function with the following signature:

```
void (*f) (void *z, const void *x) ;
```

When the function `f` is called, the arguments `z` and `x` are passed as `(void *)` pointers, but they will be pointers to values of the correct type, defined by `ztype` and `xtype`, respectively, when the operator was created.

**NOTE:** The pointers passed to a user-defined operator may not be unique. That is, the user function may be called with multiple pointers that point to the same space, such as when  $\mathbf{z} = \mathbf{f}(\mathbf{z}, \mathbf{y})$  is to be computed by a binary operator, or  $\mathbf{z} = \mathbf{f}(\mathbf{z})$  for a unary operator. Any parameters passed to the user-callable function may be aliased to each other.

### 6.2.2 GxB\_UnaryOp\_new: create a named user-defined unary operator

```
GrB_Info GxB_UnaryOp_new          // create a new user-defined unary operator
(
    GrB_UnaryOp *unaryop,          // handle for the new unary operator
    GxB_unary_function function,    // pointer to the unary function
    GrB_Type ztype,                // type of output z
    GrB_Type xtype,                // type of input x
    const char *unop_name,          // name of the user function
    const char *unop_defn           // definition of the user function
);
```

Creates a named `GrB_UnaryOp`. Only the first 127 characters of `unop_name` are used. The `unop_defn` is a string containing the entire function itself. For example:

```
void square (double *z, double *x) { (*z) = (*x) * (*x) ; } ;
...
GrB_Type Square ;
GxB_UnaryOp_new (&Square, square, GrB_FP64, GrB_FP64, "square",
    "void square (double *z, double *x) { (*z) = (*x) * (*x) ; } ;");
```

The two strings `unop_name` and `unop_defn` are optional, but are required to enable the JIT compilation of kernels that use this operator.

If JIT compilation is enabled, or if the corresponding JIT kernel has been copied into the `PreJIT` folder, the `function` may be `NULL`. In this case, a JIT kernel is compiled that contains just the user-defined function. If the JIT is disabled and the `function` is `NULL`, this method returns `GrB_NULL_POINTER`.

The above example is identical to the following usage, except that `GrB_UnaryOp_new` requires a non-`NULL` function pointer.

```
void square (double *z, double *x) { (*z) = (*x) * (*x) ; } ;
...
GrB_Type Square ;
GrB_UnaryOp_new (&Square, square, GrB_FP64, GrB_FP64) ;
GrB_set (Square, "square", GxB_JIT_C_NAME) ;
GrB_set (Square, "void square (double *z, double *x) { (*z) = (*x) * (*x) ; } ;",
    GxB_JIT_C_DEFINITION) ;
```

### 6.2.3 GrB\_UnaryOp\_wait: wait for a unary operator

```
GrB_Info GrB_wait          // wait for a user-defined unary operator
(
    GrB_UnaryOp unaryop,    // unary operator to wait for
    int mode                // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

After creating a user-defined unary operator, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing except to ensure that the `unaryop` is valid.

### 6.2.4 GrB\_UnaryOp\_free: free a user-defined unary operator

```
GrB_Info GrB_free          // free a user-created unary operator
(
    GrB_UnaryOp *unaryop    // handle of unary operator to free
) ;
```

`GrB_UnaryOp_free` frees a user-defined unary operator. Either usage:

```
GrB_UnaryOp_free (&unaryop) ;
GrB_free (&unaryop) ;
```

frees the `unaryop` and sets `unaryop` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `unaryop == NULL` on input. It does nothing at all if passed a built-in unary operator.

### 6.3 GraphBLAS binary operators: $\text{GrB\_BinaryOp}$ , $z = f(x, y)$

A binary operator is a scalar function of the form  $z = f(x, y)$ . The types of  $z$ ,  $x$ , and  $y$  need not be the same. The built-in binary operators are listed in the tables below. The notation  $T$  refers to any of the 13 built-in types, but two of those types are SuiteSparse extensions ( $\text{GxB\_FC32}$  and  $\text{GxB\_FC64}$ ). For those types, the operator name always starts with  $\text{GxB}$ , not  $\text{GrB}$ . The notation  $R$  refers to any real type (all but  $\text{FC32}$  and  $\text{FC64}$ ).

The six  $\text{GxB\_IS*}$  comparators and the  $\text{GxB\_*}$  logical operators all return a result one for true and zero for false, in the same domain  $T$  or  $R$  as their inputs. These six comparators are useful as “multiply” operators for creating semirings with non-Boolean monoids.

Binary operators for all 13 types			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
$\text{GrB\_FIRST\_T}$	$T \times T \rightarrow T$	$z = x$	first argument
$\text{GrB\_SECOND\_T}$	$T \times T \rightarrow T$	$z = y$	second argument
$\text{GxB\_ANY\_T}$	$T \times T \rightarrow T$	$z = x \text{ or } y$	pick $x$ or $y$ arbitrarily
$\text{GrB\_ONEB\_T}$	$T \times T \rightarrow T$	$z = 1$	one
$\text{GxB\_PAIR\_T}$	$T \times T \rightarrow T$	$z = 1$	one (historical)
$\text{GrB\_PLUS\_T}$	$T \times T \rightarrow T$	$z = x + y$	addition
$\text{GrB\_MINUS\_T}$	$T \times T \rightarrow T$	$z = x - y$	subtraction
$\text{GxB\_RMINUS\_T}$	$T \times T \rightarrow T$	$z = y - x$	reverse subtraction
$\text{GrB\_TIMES\_T}$	$T \times T \rightarrow T$	$z = xy$	multiplication
$\text{GrB\_DIV\_T}$	$T \times T \rightarrow T$	$z = x/y$	division
$\text{GxB\_RDIV\_T}$	$T \times T \rightarrow T$	$z = y/x$	reverse division
$\text{GxB\_POW\_T}$	$T \times T \rightarrow T$	$z = x^y$	power
$\text{GxB\_ISEQ\_T}$	$T \times T \rightarrow T$	$z = (x == y)$	equal
$\text{GxB\_ISNE\_T}$	$T \times T \rightarrow T$	$z = (x \neq y)$	not equal

The  $\text{GxB\_POW\_*}$  operators for real types do not return a complex result, and thus  $z = f(x, y) = x^y$  is undefined if  $x$  is negative and  $y$  is not an integer. To compute a complex result, use  $\text{GxB\_POW\_FC32}$  or  $\text{GxB\_POW\_FC64}$ .

Operators that require the domain to be ordered ( $\text{MIN}$ ,  $\text{MAX}$ , less-than, greater-than, and so on) are not defined for complex types. These are listed in the following table:

Binary operators for all non-complex types			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
<b>GrB_MIN_R</b>	$R \times R \rightarrow R$	$z = \min(x, y)$	minimum
<b>GrB_MAX_R</b>	$R \times R \rightarrow R$	$z = \max(x, y)$	maximum
<b>GxB_ISGT_R</b>	$R \times R \rightarrow R$	$z = (x > y)$	greater than
<b>GxB_ISLT_R</b>	$R \times R \rightarrow R$	$z = (x < y)$	less than
<b>GxB_ISGE_R</b>	$R \times R \rightarrow R$	$z = (x \geq y)$	greater than or equal
<b>GxB_ISLE_R</b>	$R \times R \rightarrow R$	$z = (x \leq y)$	less than or equal
<b>GxB_LOR_R</b>	$R \times R \rightarrow R$	$z = (x \neq 0) \vee (y \neq 0)$	logical OR
<b>GxB_LAND_R</b>	$R \times R \rightarrow R$	$z = (x \neq 0) \wedge (y \neq 0)$	logical AND
<b>GxB_LXOR_R</b>	$R \times R \rightarrow R$	$z = (x \neq 0) \vee (y \neq 0)$	logical XOR

Another set of six kinds of built-in comparators have the form  $T \times T \rightarrow \text{bool}$ . Note that when  $T$  is **bool**, the six operators give the same results as the six **GxB\_IS\*\_BOOL** operators in the table above. These six comparators are useful as “multiply” operators for creating semirings with Boolean monoids.

Binary comparators for all 13 types			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
<b>GrB_EQ_T</b>	$T \times T \rightarrow \text{bool}$	$z = (x == y)$	equal
<b>GrB_NE_T</b>	$T \times T \rightarrow \text{bool}$	$z = (x \neq y)$	not equal

Binary comparators for non-complex types			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
<b>GrB_GT_R</b>	$R \times R \rightarrow \text{bool}$	$z = (x > y)$	greater than
<b>GrB_LT_R</b>	$R \times R \rightarrow \text{bool}$	$z = (x < y)$	less than
<b>GrB_GE_R</b>	$R \times R \rightarrow \text{bool}$	$z = (x \geq y)$	greater than or equal
<b>GrB_LE_R</b>	$R \times R \rightarrow \text{bool}$	$z = (x \leq y)$	less than or equal

GraphBLAS has four built-in binary operators that operate purely in the Boolean domain. The first three are identical to the **GxB\_L\*\_BOOL** operators described above, just with a shorter name. The **GrB\_LXNOR** operator is the same as **GrB\_EQ\_BOOL**.

Binary operators for the boolean type only			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
<b>GrB_LOR</b>	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = x \vee y$	logical OR
<b>GrB_LAND</b>	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = x \wedge y$	logical AND
<b>GrB_LXOR</b>	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = x \vee y$	logical XOR
<b>GrB_LXNOR</b>	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = \neg(x \vee y)$	logical XNOR

The following operators are defined for real floating-point types only (**GrB\_FP32** and **GrB\_FP64**). They are identical to the C11 functions of the same name. The last one in the table constructs the corresponding complex type.

Binary operators for the real floating-point types only			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
<b>GxB_ATAN2_F</b>	$F \times F \rightarrow F$	$z = \tan^{-1}(y/x)$	4-quadrant arc tangent
<b>GxB_HYPOT_F</b>	$F \times F \rightarrow F$	$z = \sqrt{x^2 + y^2}$	hypotenuse
<b>GxB_FMOD_F</b>	$F \times F \rightarrow F$		C11 <code>fmod</code>
<b>GxB_REMAINDER_F</b>	$F \times F \rightarrow F$		C11 <code>remainder</code>
<b>GxB_LDEXP_F</b>	$F \times F \rightarrow F$		C11 <code>ldexp</code>
<b>GxB_COPYSIGN_F</b>	$F \times F \rightarrow F$		C11 <code>copysign</code>
<b>GxB_CMPLX_F</b>	$F \times F \rightarrow Z$	$z = x + y \times i$	complex from real & imag

Eight bitwise operators are predefined for signed and unsigned integers.

Binary operators for signed and unsigned integers			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
<b>GrB_BOR_I</b>	$I \times I \rightarrow I$	$z = x   y$	bitwise logical OR
<b>GrB_BAND_I</b>	$I \times I \rightarrow I$	$z = x \& y$	bitwise logical AND
<b>GrB_BXOR_I</b>	$I \times I \rightarrow I$	$z = x \wedge y$	bitwise logical XOR
<b>GrB_BXNOR_I</b>	$I \times I \rightarrow I$	$z = \sim(x \wedge y)$	bitwise logical XNOR
<b>GxB_BGET_I</b>	$I \times I \rightarrow I$		get bit $y$ of $x$
<b>GxB_BSET_I</b>	$I \times I \rightarrow I$		set bit $y$ of $x$
<b>GxB_BCLR_I</b>	$I \times I \rightarrow I$		clear bit $y$ of $x$
<b>GxB_BSHIFT_I</b>	$I \times \text{int8} \rightarrow I$		bit shift

There are two sets of built-in comparators in SuiteSparse:GraphBLAS, but they are not redundant. They are identical except for the type (domain) of their output,  $z$ . The **GrB\_EQ\_T** and related operators compare their inputs of type  $T$  and produce a Boolean result of true or false. The **GxB\_ISEQ\_T** and related operators compute the same thing and produce a result with same type  $T$  as their input operands, returning one for true or zero for false. The **IS\*** comparators are useful when combining comparators with other non-Boolean operators. For example, a **PLUS-ISEQ** semiring counts how many terms are true. With this semiring, matrix multiplication  $\mathbf{C} = \mathbf{AB}$  for two weighted undirected graphs  $\mathbf{A}$  and  $\mathbf{B}$  computes  $c_{ij}$  as the number of edges node  $i$  and  $j$  have in common that have identical edge weights. Since the output type of the “multiplier” operator in a semiring must match the type

of its monoid, the Boolean `EQ` cannot be combined with a non-Boolean `PLUS` monoid to perform this operation.

Likewise, SuiteSparse:GraphBLAS has two sets of logical OR, AND, and XOR operators. Without the `_T` suffix, the three operators `GrB_LOR`, `GrB LAND`, and `GrB_LXOR` operate purely in the Boolean domain, where all input and output types are `GrB_BOOL`. The second set (`GxB_LOR_T`, `GxB LAND_T` and `GxB_LXOR_T`) provides Boolean operators to all 11 real domains, implicitly typecasting their inputs from type `T` to Boolean and returning a value of type `T` that is 1 for true or zero for false. The set of `GxB_L*_T` operators are useful since they can be combined with non-Boolean monoids in a semiring.

Floating-point operations follow the IEEE 754 standard. Thus, computing  $x/0$  for a floating-point  $x$  results in `+Inf` if  $x$  is positive, `-Inf` if  $x$  is negative, and `NaN` if  $x$  is zero. The application is not terminated. However, integer division by zero normally terminates an application. SuiteSparse:GraphBLAS avoids this by adopting the same rules as MATLAB, which are analogous to how the IEEE standard handles floating-point division by zero. For integers, when  $x$  is positive,  $x/0$  is the largest positive integer, for negative  $x$  it is the minimum integer, and  $0/0$  results in zero. For example, for an integer  $x$  of type `GrB_INT32`,  $1/0$  is  $2^{31} - 1$  and  $(-1)/0$  is  $-2^{31}$ . Refer to Section 6.1 for a list of integer ranges.

### 6.3.1 GraphBLAS binary operators based on index binary operators

Eight binary operators based on underlying index binary operators are predefined. They differ when used in a semiring and when used in `GrB_eWise*` and `GrB_apply`. These index-based binary operators cannot be used in `GrB_build`, nor can they be used as the `accum` operator for any operation.

The built-in index-based binary operators do not depend on the type or numerical value of their inputs, just their position in a matrix or vector. For a vector,  $j$  is always 0, and  $i$  is the index into the vector. There are two types  $N$  available: `INT32` and `INT64`, which is the type of the output  $z$ . User-defined index-based operators are not defined by `GrB_BinaryOp_new`, but by `GxB_BinaryOp_new_IndexOp` instead. See Section 6.5 for details.

Index-based binary operators for any type (including user-defined) when used as a multiplicative operator in a semiring			
GraphBLAS name	types (domains)	$z = f(a_{ik}, b_{kj})$	description
GxB_FIRSTI_N	$\rightarrow N$	$z = i$	row index of $a_{ik}$ (0-based)
GxB_FIRSTI1_N	$\rightarrow N$	$z = i + 1$	row index of $a_{ik}$ (1-based)
GxB_FIRSTJ_N	$\rightarrow N$	$z = k$	column index of $a_{ik}$ (0-based)
GxB_FIRSTJ1_N	$\rightarrow N$	$z = k + 1$	column index of $a_{ik}$ (1-based)
GxB_SECONDI_N	$\rightarrow N$	$z = k$	row index of $b_{kj}$ (0-based)
GxB_SECONDI1_N	$\rightarrow N$	$z = k + 1$	row index of $b_{kj}$ (1-based)
GxB_SECONDJ_N	$\rightarrow N$	$z = j$	column index of $b_{kj}$ (0-based)
GxB_SECONDJ1_N	$\rightarrow N$	$z = j + 1$	column index of $b_{kj}$ (1-based)

Index-based binary operators for any type (including user-defined) when used in all other methods			
GraphBLAS name	types (domains)	$z = f(a_{ij}, b_{ij})$	description
GxB_FIRSTI_N	$\rightarrow N$	$z = i$	row index of $a_{ij}$ (0-based)
GxB_FIRSTI1_N	$\rightarrow N$	$z = i + 1$	row index of $a_{ij}$ (1-based)
GxB_FIRSTJ_N	$\rightarrow N$	$z = j$	column index of $a_{ij}$ (0-based)
GxB_FIRSTJ1_N	$\rightarrow N$	$z = j + 1$	column index of $a_{ij}$ (1-based)
GxB_SECONDI_N	$\rightarrow N$	$z = i$	row index of $b_{ij}$ (0-based)
GxB_SECONDI1_N	$\rightarrow N$	$z = i + 1$	row index of $b_{ij}$ (1-based)
GxB_SECONDJ_N	$\rightarrow N$	$z = j$	column index of $b_{ij}$ (0-based)
GxB_SECONDJ1_N	$\rightarrow N$	$z = j + 1$	column index of $b_{ij}$ (1-based)

Finally, one special binary operator can only be used as input to `GrB_Matrix_build` or `GrB_Vector_build`: the `GxB_IGNORE_DUP` operator. If `dup` is `NULL`, any duplicates in the `GrB*build` methods result in an error. If `dup` is the special binary operator `GxB_IGNORE_DUP`, then any duplicates are ignored. If duplicates appear, the last one in the list of tuples is taken and the prior ones ignored. This is not an error.

The next sections define the following methods for the `GrB_BinaryOp` object:

GraphBLAS function	purpose	Section
<code>GrB_BinaryOp_new</code>	create a user-defined binary operator	<a href="#">6.3.2</a>
<code>GxB_BinaryOp_new</code>	create a named user-defined binary operator	<a href="#">6.3.3</a>
<code>GrB_BinaryOp_wait</code>	wait for a user-defined binary operator	<a href="#">6.3.4</a>
<code>GrB_BinaryOp_free</code>	free a user-defined binary operator	<a href="#">6.3.5</a>
<code>GrB_get</code>	get properties of an operator	<a href="#">10.6</a>
<code>GrB_set</code>	set the operator name/definition	<a href="#">10.6</a>

### 6.3.2 GrB\_BinaryOp\_new: create a user-defined binary operator

```
GrB_Info GrB_BinaryOp_new
(
    GrB_BinaryOp *binaryop,      // handle for the new binary operator
    void *function,              // pointer to the binary function
    GrB_Type ztype,              // type of output z
    GrB_Type xtype,              // type of input x
    GrB_Type ytype               // type of input y
) ;
```

`GrB_BinaryOp_new` creates a new binary operator. The new operator is returned in the `binaryop` handle, which must not be NULL on input. On output, its contents contains a pointer to the new binary operator.

The three types `xtype`, `ytype`, and `ztype` are the GraphBLAS types of the inputs  $x$  and  $y$ , and output  $z$  of the user-defined function  $z = f(x, y)$ . These types may be built-in types or user-defined types, in any combination. The three types need not be the same, but they must be previously defined before passing them to `GrB_BinaryOp_new`.

The final argument to `GrB_BinaryOp_new` is a pointer to a user-defined function with the following signature:

```
void (*f) (void *z, const void *x, const void *y) ;
```

When the function `f` is called, the arguments `z`, `x`, and `y` are passed as `(void *)` pointers, but they will be pointers to values of the correct type, defined by `ztype`, `xtype`, and `ytype`, respectively, when the operator was created.

**NOTE:** SuiteSparse:GraphBLAS may call the function with the pointers `z` and `x` equal to one another, in which case  $\mathbf{z}=\mathbf{f}(\mathbf{z},\mathbf{y})$  should be computed. Future versions may use additional pointer aliasing.

### 6.3.3 GrB\_BinaryOp\_new: create a named user-defined binary operator

```
GrB_Info GrB_BinaryOp_new
(
    GrB_BinaryOp *op,           // handle for the new binary operator
    GxB_binary_function function, // pointer to the binary function
    GrB_Type ztype,             // type of output z
    GrB_Type xtype,             // type of input x
    GrB_Type ytype,             // type of input y
    const char *binop_name,      // name of the user function
    const char *binop_defn       // definition of the user function
) ;
```

Creates a named `GrB_BinaryOp`. Only the first 127 characters of `binop_name` are used. The `binop_defn` is a string containing the entire function itself. For example:

```
void absdiff (double *z, double *x, double *y) { (*z) = fabs ((*x) - (*y)) ; } ;
...
GrB_Type AbsDiff ;
GrB_BinaryOp_new (&AbsDiff, absdiff, GrB_FP64, GrB_FP64, GrB_FP64, "absdiff",
    "void absdiff (double *z, double *x, double *y) { (*z) = fabs ((*x) - (*y)) ; }") ;
```

The two strings `binop_name` and `binop_defn` are optional, but are required to enable the JIT compilation of kernels that use this operator.

If the JIT is enabled, or if the corresponding JIT kernel has been copied into the `PreJIT` folder, the `function` may be `NULL`. In this case, a JIT kernel is compiled that contains just the user-defined function. If the JIT is disabled and the `function` is `NULL`, this method returns `GrB_NULL_POINTER`.

The above example is identical to the following usage, except that `GrB_BinaryOp_new` requires a non-`NULL` function pointer.

```
void absdiff (double *z, double *x, double *y) { (*z) = fabs ((*x) - (*y)) ; } ;
...
GrB_Type AbsDiff ;
GrB_BinaryOp_new (&AbsDiff, absdiff, GrB_FP64, GrB_FP64, GrB_FP64) ;
GrB_set (AbsDiff, "absdiff", GxB_JIT_C_NAME) ;
GrB_set (AbsDiff,
    "void absdiff (double *z, double *x, double *y) { (*z) = fabs ((*x) - (*y)) ; }",
    GxB_JIT_C_DEFINITION) ;
```

#### 6.3.4 GrB\_BinaryOp\_wait: wait for a binary operator

```
GrB_Info GrB_wait          // wait for a user-defined binary operator
(
    GrB_BinaryOp binaryop,  // binary operator to wait for
    int mode                // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

After creating a user-defined binary operator, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing for except to ensure that the `binaryop` is valid.

#### 6.3.5 GrB\_BinaryOp\_free: free a user-defined binary operator

```
GrB_Info GrB_free          // free a user-created binary operator
(
    GrB_BinaryOp *binaryop  // handle of binary operator to free
) ;
```

`GrB_BinaryOp_free` frees a user-defined binary operator. Either usage:

```
GrB_BinaryOp_free (&op) ;
GrB_free (&op) ;
```

frees the `op` and sets `op` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `op == NULL` on input. It does nothing at all if passed a built-in binary operator.

#### 6.3.6 ANY and PAIR (ONEB) operators

The `GxB_PAIR` operator (also called `GrB_ONEB`) is simple to describe: just  $f(x, y) = 1$ . It is called the `PAIR` operator since it returns 1 in a semiring when a pair of entries  $a_{ik}$  and  $b_{kj}$  is found in the matrix multiply. This operator is simple yet very useful. It allows purely structural computations to be performed on matrices of any type, without having to typecast them to Boolean with all values being true. Typecasting need not be performed on the inputs to the `PAIR` operator, and the `PAIR` operator does not need to access the values of the matrix. This cuts memory accesses, so it is a very fast operator to use.

The `GxB_PAIR_T` operator is a SuiteSparse:GraphBLAS extension. It has since been added to the v2.0 C API Specification as `GrB_ONEB_T`. They are identical, but the latter name should be used for compatibility with other GraphBLAS libraries.

The `ANY` operator is very unusual, but very powerful. It is the function  $f_{\text{any}}(x, y) = x$ , or  $y$ , where GraphBLAS has to freedom to select either  $x$ , or  $y$ , at its own discretion. Do not confuse the `ANY` operator with the `any` function in MATLAB/Octave, which computes a reduction using the logical OR operator.

The `ANY` function is associative and commutative, and can thus serve as an operator for a monoid. The selection of  $x$  or  $y$  is not randomized. Instead, SuiteSparse:GraphBLAS uses this freedom to compute as fast a result as possible. When used as the monoid in a dot product,

$$c_{ij} = \sum_k a_{ik} b_{kj}$$

for example, the computation can terminate as soon as any matching pair of entries is found. When used in a parallel saxpy-style computation, the `ANY` operator allows for a relaxed form of synchronization to be used, resulting in a fast benign race condition.

Because of this benign race condition, the result of the `ANY` monoid can be non-deterministic, unless it is coupled with the `PAIR` multiplicative operator. In this case, the `ANY_PAIR` semiring will return a deterministic result, since  $f_{\text{any}}(1, 1)$  is always 1.

When paired with a different operator, the results are non-deterministic. This gives a powerful method when computing results for which any value selected by the `ANY` operator is valid. One such example is the breadth-first-search tree. Suppose node  $j$  is at level  $v$ , and there are multiple nodes  $i$  at level  $v - 1$  for which the edge  $(i, j)$  exists in the graph. Any of these nodes  $i$  can serve as a valid parent in the BFS tree. Using the `ANY` operator, GraphBLAS can quickly compute a valid BFS tree; if it used again on the same inputs, it might return a different, yet still valid, BFS tree, due to the non-deterministic nature of intra-thread synchronization.

## 6.4 GraphBLAS IndexUnaryOp operators: GrB\_IndexUnaryOp

An index-unary operator is a scalar function of the form  $z = f(a_{ij}, i, j, y)$  that is applied to the entries  $a_{ij}$  of an  $m$ -by- $n$  matrix. It can be used in `GrB_apply` (Section 12.12) or in `GrB_select` (Section 12.13) to select entries from a matrix or vector.

The signature of the index-unary function `f` is as follows:

```
void f
(
    void *z,           // output value z, of type ztype
    const void *x,      // input value x of type xtype; value of v(i) or A(i,j)
    GrB_Index i,        // row index of A(i,j)
    GrB_Index j,        // column index of A(i,j), or zero for v(i)
    const void *y       // input scalar y of type ytype
) ;
```

The following built-in operators are available. Operators that do not depend on the value of `A(i,j)` can be used on any matrix or vector, including those of user-defined type. In the table, `y` is a scalar whose type matches the suffix of the operator. The `VALUEEQ` and `VALUENE` operators are defined for any built-in type. The other `VALUE` operators are defined only for real (not complex) built-in types. Any index computations are done in `int64_t` arithmetic; the result is typecasted to `int32_t` for the `*INDEX_INT32` operators.

GraphBLAS name	MATLAB/Octave analog	description
GrB_ROWINDEX_INT32	$z=i+y$	row index of $A(i,j)$ , as int32
GrB_ROWINDEX_INT64	$z=i+y$	row index of $A(i,j)$ , as int64
GrB_COLINDEX_INT32	$z=j+y$	column index of $A(i,j)$ , as int32
GrB_COLINDEX_INT64	$z=j+y$	column index of $A(i,j)$ , as int64
GrB_DIAGINDEX_INT32	$z=j-(i+y)$	column diagonal index of $A(i,j)$ , as int32
GrB_DIAGINDEX_INT64	$z=j-(i+y)$	column diagonal index of $A(i,j)$ , as int64
GrB_TRIL	$z=(j \leq (i+y))$	true for entries on or below the $y$ th diagonal
GrB_TRIU	$z=(j \geq (i+y))$	true for entries on or above the $y$ th diagonal
GrB_DIAG	$z=(j == (i+y))$	true for entries on the $y$ th diagonal
GrB_OFFDIAG	$z=(j \neq (i+y))$	true for entries not on the $y$ th diagonal
GrB_COLLE	$z=(j \leq y)$	true for entries in columns 0 to $y$
GrB_COLGT	$z=(j > y)$	true for entries in columns $y+1$ and above
GrB_ROWLE	$z=(i \leq y)$	true for entries in rows 0 to $y$
GrB_ROWGT	$z=(i > y)$	true for entries in rows $y+1$ and above
GrB_VALUENE_T	$z=(a_{ij} \neq y)$	true if $A(i,j)$ is not equal to $y$
GrB_VALUEEQ_T	$z=(a_{ij} == y)$	true if $A(i,j)$ is equal to $y$
GrB_VALUEGT_T	$z=(a_{ij} > y)$	true if $A(i,j)$ is greater than $y$
GrB_VALUEGE_T	$z=(a_{ij} \geq y)$	true if $A(i,j)$ is greater than or equal to $y$
GrB_VALUELT_T	$z=(a_{ij} < y)$	true if $A(i,j)$ is less than $y$
GrB_VALUELE_T	$z=(a_{ij} \leq y)$	true if $A(i,j)$ is less than or equal to $y$

The following methods operate on the `GrB_IndexUnaryOp` object:

GraphBLAS function	purpose	Section
<code>GrB_IndexUnaryOp_new</code>	create a user-defined index-unary operator	<a href="#">6.4.1</a>
<code>GxB_IndexUnaryOp_new</code>	create a named user-defined index-unary operator	<a href="#">6.4.2</a>
<code>GrB_IndexUnaryOp_wait</code>	wait for a user-defined index-unary operator	<a href="#">6.4.3</a>
<code>GrB_IndexUnaryOp_free</code>	free a user-defined index-unary operator	<a href="#">6.4.4</a>
<code>GrB_get</code>	get properties of an operator	<a href="#">10.5</a>
<code>GrB_set</code>	set the operator name/definition	<a href="#">10.5</a>

#### 6.4.1 GrB\_IndexUnaryOp\_new: create a user-defined index-unary operator

```
GrB_Info GrB_IndexUnaryOp_new      // create a new user-defined IndexUnary op
(
    GrB_IndexUnaryOp *op,          // handle for the new IndexUnary operator
    void *function,                // pointer to IndexUnary function
    GrB_Type ztype,                // type of output z
    GrB_Type xtype,                // type of input x (the A(i,j) entry)
    GrB_Type ytype                 // type of scalar input y
);
```

`GrB_IndexUnaryOp_new` creates a new index-unary operator. The new operator is returned in the `op` handle, which must not be `NULL` on input. On output, its contents contains a pointer to the new index-unary operator.

The `function` argument to `GrB_IndexUnaryOp_new` is a pointer to a user-defined function whose signature is given at the beginning of Section 6.4. Given the properties of an entry  $a_{ij}$  in a matrix, the `function` should return `z` as `true` if the entry should be kept in the output of `GrB_select`, or `false` if it should not appear in the output. If the return value is not `GrB_BOOL`, it is typecasted to `GrB_BOOL` by `GrB_select`.

The type `xtype` is the GraphBLAS type of the input  $x$  of the user-defined function  $z = f(x, i, j, y)$ , which is used for the entry  $A(i, j)$  of a matrix or  $v(i)$  of a vector. The type may be built-in or user-defined.

The type `ytype` is the GraphBLAS type of the scalar input  $y$  of the user-defined function  $z = f(x, i, j, y)$ . The type may be built-in or user-defined.

### 6.4.2 GrB\_IndexUnaryOp\_new: create a named user-defined index-unary operator

```
GrB_Info GrB_IndexUnaryOp_new  // create a named user-created IndexUnaryOp
(
    GrB_IndexUnaryOp *op,          // handle for the new IndexUnary operator
    GrB_index_unary_function function, // pointer to index_unary function
    GrB_Type ztype,              // type of output z
    GrB_Type xtype,              // type of input x
    GrB_Type ytype,              // type of scalar input y
    const char *idxop_name,       // name of the user function
    const char *idxop_defn        // definition of the user function
) ;
```

Creates a named `GrB_IndexUnaryOp`. Only the first 127 characters of `idxop_name` are used. The `idxop_defn` is a string containing the entire function itself.

The two strings `idxop_name` and `idxop_defn` are optional, but are required to enable the JIT compilation of kernels that use this operator. The strings can also be set the `GrB_set` after the operator is created with `GrB_IndexUnaryOp_new`. For example:

```
void banded_idx
(
    bool *z,
    const int64_t *x,  // unused
    int64_t i,
    int64_t j,
    const int64_t *thunk
)
{
    // d = abs (j-i)
    int64_t d = j-i ;
    if (d < 0) d = -d ;
    (*z) = (d <= *thunk) ;
}

#define BANDED_IDX_DEFN \
"void banded_idx      \n" \
"(\n                  \n" \
"    bool *z,         \n" \
"    const int64_t *x, // unused \n" \
"    int64_t i,       \n" \
"    int64_t j,       \n"
```

```

"    const int64_t *thunk          \n" \
")                                \n" \
"{                                \n" \
"    int64_t d = j-i ;            \n" \
"    if (d < 0) d = -d ;          \n" \
"    (*z) = (d <= *thunk) ;       \n" \
"}"

```

```

GrB_IndexUnaryOp_new (&Banded,
    (GxB_index_unary_function) banded_idx,
    GrB_BOOL, GrB_INT64, GrB_INT64,
    "banded_idx", BANDED_IDX_DEFN)) ;

```

If JIT compilation is enabled, or if the corresponding JIT kernel has been copied into the `PreJIT` folder, the `function` may be `NULL`. In this case, a JIT kernel is compiled that contains just the user-defined function. If the JIT is disabled and the `function` is `NULL`, this method returns `GrB_NULL_POINTER`.

The above example is identical to the following usage except that `GrB_IndexUnaryOp_new` requires a non-`NULL` function pointer. The `banded_idx` function is defined the same as above.

```

void banded_idx ... see above
#define BANDED_IDX_DEFN ... see above

GrB_IndexUnaryOp_new (&Banded,
    (GxB_index_unary_function) banded_idx,
    GrB_BOOL, GrB_INT64, GrB_INT64) ;
GrB_set (Banded, "banded_idx", GxB_JIT_C_NAME)) ;
GrB_set (Banded, BANDED_IDX_DEFN, GxB_JIT_C_DEFINITION)) ;

```

#### 6.4.3 GrB\_IndexUnaryOp\_wait: wait for an index-unary operator

```

GrB_Info GrB_wait          // wait for a user-defined binary operator
(
    GrB_IndexUnaryOp op,    // index-unary operator to wait for
    int mode                // GrB_COMPLETE or GrB_MATERIALIZE
) ;

```

After creating a user-defined index-unary operator, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing except to ensure that the `op` is valid.

#### 6.4.4 GrB\_IndexUnaryOp\_free: free a user-defined index-unary operator

```
GrB_Info GrB_free          // free a user-created index-unary operator
(
    GrB_IndexUnaryOp *op    // handle of IndexUnary to free
) ;
```

GrB\_IndexUnaryOp\_free frees a user-defined index-unary operator. Either usage:

```
GrB_IndexUnaryOp_free (&op) ;
GrB_free (&op) ;
```

frees the op and sets op to NULL. It safely does nothing if passed a NULL handle, or if op == NULL on input. It does nothing at all if passed a built-in index-unary operator.

## 6.5 GraphBLAS index-binary operators: GxB\_IndexBinaryOp

An index-binary operator is a scalar function of the following form:

$$z = f(x, i_x, j_x, y, i_y, j_y, \Theta),$$

where the value  $x$  appears at row  $i_x$  and column  $j_x$  in its matrix, and the value  $y$  appears at row  $i_y$  and column  $j_y$  in its matrix. The value  $\Theta$  is a scalar that is the same for all uses of the operator. See our IEEE HPEC'24 paper for more details ([MBM<sup>+</sup>24]), in the GraphBLAS/Doc folder.

When used in an element-wise method for  $\mathbf{C} = \mathbf{A} \oplus \mathbf{B}$  and related methods (`GrB_eWiseAdd`, `GxB_eWiseUnion`, or `GrB_eWiseMult`), operator is used for a pair of entries  $a_{ij}$  and  $b_{ij}$ , as

$$z = f(a_{ij}, i, j, b_{ij}, i, j, \Theta).$$

When used in `GrB_kronecker`, it is used on a pair of entries  $a_{i_1, j_1}$  and  $b_{i_2, j_2}$ , as

$$z = f(a_{ij}, i_1, j_1, b_{ij}, i_2, j_2, \Theta).$$

When used as the multiplicative operator in a semiring, to compute  $\mathbf{C} = \mathbf{A} \oplus . \otimes \mathbf{B}$ , the operator is used as

$$z = f(a_{ik}, i, k, b_{kj}, k, j, \Theta)$$

to compute an entry to be summed by the monoid of the semiring.

No GraphBLAS operations directly use the `GxB_IndexBinaryOp`. Instead, the operator is coupled with a scalar `Theta` value to create a new index-based binary operator, which is simply a special case of a `GrB_BinaryOp`. The resulting `GrB_BinaryOp` can then be passed to element-wise methods and as the multiplicative operator of a new semiring.

The signature of the index-binary function `f` is as follows:

```
void f
(
    void *z,           // output value z, of type ztype
    const void *x,     // input value x of type xtype; value of v(ix) or A(ix,jx)
    GrB_Index ix,      // row index of v(ix) or A(ix,jx)
    GrB_Index jx,      // column index of A(ix,jx), or zero for v(ix)
    const void *y,     // input value y of type ytype; value of w(iy) or B(iy,jy)
    GrB_Index iy,      // row index of w(iy) or B(iy,jy)
    GrB_Index jy,      // column index of B(iy,jy), or zero for w(iy)
    const void *theta   // input scalar theta of type theta_type
) ;
```

The following binary operators (`GrB_BinaryOp` objects) are pre-defined, where  $N$  can be `INT32` or `INT64`. These operators do not use `theta`. Instead, the offset of 1 in `GxB_FIRSTI1` is fixed into the operator itself.

Built-in index-based binary operators for any type			
GraphBLAS name	types (domains)	$z = f(x, y)$	description
<code>GxB_FIRSTI_N</code>	$\rightarrow N$	$z = i_x$	row index of $x$ (0-based)
<code>GxB_FIRSTI1_N</code>	$\rightarrow N$	$z = i_x + 1$	row index of $x$ (1-based)
<code>GxB_FIRSTJ_N</code>	$\rightarrow N$	$z = j_x$	column index of $x$ (0-based)
<code>GxB_FIRSTJ1_N</code>	$\rightarrow N$	$z = j_x + 1$	column index of $x$ (1-based)
<code>GxB_SECONDI_N</code>	$\rightarrow N$	$z = i_y$	row index of $y$ (0-based)
<code>GxB_SECONDI1_N</code>	$\rightarrow N$	$z = i_y + 1$	row index of $y$ (1-based)
<code>GxB_SECONDJ_N</code>	$\rightarrow N$	$z = j_y$	column index of $y$ (0-based)
<code>GxB_SECONDJ1_N</code>	$\rightarrow N$	$z = j_y + 1$	column index of $y$ (1-based)

The following methods operate on the `GxB_IndexBinaryOp` object:

GraphBLAS function	purpose	Section
<code>GxB_IndexBinaryOp_new</code>	create a named user-defined index-binary operator	<a href="#">6.5.1</a>
<code>GxB_IndexBinaryOp_wait</code>	wait for a user-defined index-binary operator	<a href="#">6.5.2</a>
<code>GxB_IndexBinaryOp_free</code>	free a user-defined index-binary operator	<a href="#">6.5.3</a>
<code>GxB_BinaryOp_new_IndexOp</code>	create a new index-based <code>GrB_BinaryOp</code>	<a href="#">6.5.4</a>
<code>GrB_get</code>	get properties of an operator	<a href="#">10.7</a>
<code>GrB_set</code>	set the operator name/definition	<a href="#">10.7</a>

### 6.5.1 GxB\_IndexBinaryOp\_new: create a user-defined index-binary operator

```

GrB_Info GxB_IndexBinaryOp_new
(
    GxB_IndexBinaryOp *op,           // handle for the new index binary operator
    GxB_index_binary_function function, // pointer to the index binary function
    GrB_Type ztype,                 // type of output z
    GrB_Type xtype,                 // type of input x
    GrB_Type ytype,                 // type of input y
    GrB_Type theta_type,            // type of input theta
    const char *idxbinop_name,      // name of the user function
    const char *idxbinop_defn       // definition of the user function
) ;

```

Creates a named `GxB_IndexBinaryOp`. Only the first 127 characters of `idxbinop_name` are used. The `idxbinop_defn` is a string containing the entire function itself.

The two strings `idxbinop_name` and `idxbinop_defn` are optional, but are required to enable the JIT compilation of kernels that use this operator. For example, the following operator can be used to compute the argmax of a matrix with a single call to `GrB_mxv`. It returns a vector `c` where  $c(i) = (k, v)$ , where the largest value in the  $i$ th row of  $A$  has value  $v$  and appears in column  $k$ . If multiple values in the  $i$ th row have the same largest value, the one with the smallest column index is returned.

```

typedef struct { int64_t k ; double v ; } tuple_fp64 ;
#define FP64_K "typedef struct { int64_t k ; double v ; } tuple_fp64 ;"
void make_fp64 (tuple_fp64 *z,
    const double *x, GrB_Index ix, GrB_Index jx,
    const void *y, GrB_Index iy, GrB_Index jy,
    const void *theta)
{
    z->k = (int64_t) jx ;
    z->v = (*x) ;
}
void max_fp64 (tuple_fp64 *z, const tuple_fp64 *x, const tuple_fp64 *y)
{
    if (x->v > y->v || (x->v == y->v && x->k < y->k))
    {
        z->k = x->k ;
        z->v = x->v ;
    }
    else

```

```

    {
        z->k = y->k ;
        z->v = y->v ;
    }
}

#define MAX_FP64 (a string containing the max_fp64 function above)

// create the types and operators:
GrB_Scalar Theta ; // unused, but cannot be NULL
GrB_Scalar_new (&Theta, GrB_BOOL) ;
GrB_Scalar_setElement_BOOL (Theta, 0) ;
GxB_IndexBinaryOp Iop ;
GrB_BinaryOp Bop, MonOp ;
GrB_Type Tuple ;
GxB_Type_new (&Tuple, sizeof (tuple_fp64), "tuple_fp64", FP64_K) ;
GxB_IndexBinaryOp_new (&Iop, make_fp64, Tuple, GrB_FP64, GrB_BOOL, GrB_BOOL,
    "make_fp64", MAKE_FP64) ;
GxB_BinaryOp_new_IndexOp (&Bop, Iop, Theta) ;
tuple_fp64 id ;
memset (&id, 0, sizeof (tuple_fp64)) ;
id.k = INT64_MAX ;
id.v = (double) (-INFINITY) ;
GxB_BinaryOp_new (&MonOp, max_fp64, Tuple, Tuple, Tuple, "max_fp64", MAX_FP64) ;
GrB_Monoid MonOp ;
GrB_Semiring Semiring ;
GrB_Monoid_new_UDT (&Monoid, MonOp, &id) ;
GrB_Semiring_new (&Semiring, Monoid, Bop) ;

// compute the argmax of each row of a GrB_FP64 matrix A:
// y = zeros (ncols,1) ;
GrB_Vector y ;
GrB_Matrix_new (&y, GrB_BOOL, ncols, 1) ;
GrB_Matrix_assign_BOOL (y, NULL, NULL, 0, GrB_ALL, ncols, GrB_ALL, 1, NULL) ;
// c = A*y using the argmax semiring
GrB_Vector_new (&c, Tuple, nrow, 1) ;
GrB_mxv (c, NULL, NULL, Semiring, A, y, NULL) ;

```

### 6.5.2 GxB\_IndexBinaryOp\_wait: wait for an index-binary operator

```
GrB_Info GxB_IndexBinaryOp_wait
(
    GxB_IndexBinaryOp op,
    int mode                // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

After creating a user-defined index-binary operator, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing except to ensure that the `op` is valid.

### 6.5.3 GxB\_IndexBinaryOp\_free: free a user-defined index-binary operator

```
GrB_Info GrB_free                // free a user-created index-binary operator
(
    GxB_IndexBinaryOp *op        // handle of IndexBinaryOp to free
) ;
```

`GxB_IndexBinaryOp_free` frees a user-defined index-binary operator. Either usage:

```
GxB_IndexBinaryOp_free (&op) ;
GrB_free (&op) ;
```

frees the `op` and sets `op` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `op == NULL` on input. No built-in index-binary operators exist, but if they did, the method does nothing at all if passed a built-in index-binary operator.

#### 6.5.4 GxB\_BinaryOp\_new\_IndexOp: create a index-based binary operator

```
GrB_Info GxB_BinaryOp_new_IndexOp
(
    GrB_BinaryOp *binop,          // handle of binary op to create
    GrB_IndexBinaryOp idxbinop,   // based on this index binary op
    GrB_Scalar theta              // theta value to bind to the new binary op
) ;
```

The `GxB_IndexBinaryOp` cannot be directly used in any GraphBLAS operation such as `GrB_mxm`. Instead, it must be used to create a new index-based `GrB_BinaryOp`. The resulting binary operator can then be used to as the multiplicative operator in a new user-defined semiring, or as the primary binary operator of the element-wise operations (`eWiseAdd`, `eWiseUnion`, `eWiseMult`, or `kronecker`).

The resulting binary operator cannot be used as the `accum` operator in any GraphBLAS operation. It also cannot be used in other places where a binary operator appears, including `GrB*_build`, `GrB_apply`, `GrB_reduce` and `GrB*_sort`.

The `GxB_BinaryOp_new_IndexOp` method creates this index-based binary operator. It takes two input parameters: an index-binary operator, and a scalar `Theta`. The value of `Theta` is copied into this new binary operator, and the value cannot be changed. To change `Theta`, the binary operator must be freed, and any semiring that would like to use the new value of `Theta` must also be recreated.

An example of its use is given in Section [6.5.1](#).

## 6.6 GraphBLAS monoids: GrB\_Monoid

A *monoid* is defined on a single domain (that is, a single type),  $T$ . It consists of an associative binary operator  $z = f(x, y)$  whose three operands  $x$ ,  $y$ , and  $z$  are all in this same domain  $T$  (that is  $T \times T \rightarrow T$ ). The operator must also have an identity element, or “zero” in this domain, such that  $f(x, 0) = f(0, x) = x$ . Recall that an associative operator  $f(x, y)$  is one for which the condition  $f(a, f(b, c)) = f(f(a, b), c)$  always holds. That is, operator can be applied in any order and the results remain the same. If used in a semiring, the operator must also be commutative.

The 77 predefined monoids are listed in the table below, which includes nearly all monoids that can be constructed from built-in binary operators. A few additional monoids can be defined with `GrB_Monoid_new` using built-in operators, such as bitwise monoids for signed integers. Recall that  $T$  denotes any built-in type (including boolean, integer, floating point real, and complex),  $R$  denotes any non-complex type (including bool),  $I$  denotes any integer type, and  $Z$  denotes any complex type. Let  $S$  denote the 10 non-boolean real types. Let  $U$  denote all unsigned integer types.

The table lists the GraphBLAS monoid, its type, expression, identity value, and *terminal* value (if any). For these built-in monoids, the terminal values are the *annihilators* of the function, which is the value  $z$  so that  $z = f(z, y)$  regardless of the value of  $y$ . For example  $\min(-\infty, y) = -\infty$  for any  $y$ . For integer domains,  $+\infty$  and  $-\infty$  are the largest and smallest integer in their range. With unsigned integers, the smallest value is zero, and thus `GrB_MIN_MONOID_UINT8` has an identity of 255 and a terminal value of 0.

When computing with a monoid, the computation can terminate early if the terminal value arises. No further work is needed since the result will not change. This value is called the terminal value instead of the annihilator, since a user-defined operator can be created with a terminal value that is not an annihilator. See Section 6.6.3 for an example.

The `GxB_ANY_*` monoid can terminate as soon as it finds any value at all.

GraphBLAS operator	types (domains)	expression	identity	terminal
		$z = f(x, y)$		
GrB_PLUS_MONOID_S	$S \times S \rightarrow S$	$z = x + y$	0	none
GrB_TIMES_MONOID_S	$S \times S \rightarrow S$	$z = xy$	1	0 or none (see note)
GrB_MIN_MONOID_S	$S \times S \rightarrow S$	$z = \min(x, y)$	$+\infty$	$-\infty$
GrB_MAX_MONOID_S	$S \times S \rightarrow S$	$z = \max(x, y)$	$-\infty$	$+\infty$
GxB_PLUS_Z_MONOID	$Z \times Z \rightarrow Z$	$z = x + y$	0	none
GxB_TIMES_Z_MONOID	$Z \times Z \rightarrow Z$	$z = xy$	1	none
GxB_ANY_T_MONOID	$T \times T \rightarrow T$	$z = x \text{ or } y$	any	any
GrB_LOR_MONOID	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = x \vee y$	false	true
GrB_LAND_MONOID	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = x \wedge y$	true	false
GrB_LXOR_MONOID	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = x \underline{\vee} y$	false	none
GrB_LXNOR_MONOID	$\text{bool} \times \text{bool} \rightarrow \text{bool}$	$z = (x == y)$	true	none
GxB_BOR_U_MONOID	$U \times U \rightarrow U$	$\mathbf{z} = \mathbf{x} \mid \mathbf{y}$	all bits zero	all bits one
GxB_BAND_U_MONOID	$U \times U \rightarrow U$	$\mathbf{z} = \mathbf{x} \& \mathbf{y}$	all bits one	all bits zero
GxB_BXOR_U_MONOID	$U \times U \rightarrow U$	$\mathbf{z} = \mathbf{x} \wedge \mathbf{y}$	all bits zero	none
GxB_BXNOR_U_MONOID	$U \times U \rightarrow U$	$\mathbf{z} = \sim(\mathbf{x} \wedge \mathbf{y})$	all bits one	none

The C API Specification includes 44 predefined monoids, with the naming convention `GrB_op_MONOID_type`. Forty monoids are available for the four operators MIN, MAX, PLUS, and TIMES, each with the 10 non-boolean real types. Four boolean monoids are predefined: `GrB_LOR_MONOID_BOOL`, `GrB_LAND_MONOID_BOOL`, `GrB_LXOR_MONOID_BOOL`, and `GrB_LXNOR_MONOID_BOOL`.

These all appear in SuiteSparse:GraphBLAS, which adds 33 additional predefined `GxB*` monoids, with the naming convention `GxB_op_type_MONOID`. The ANY operator can be used for all 13 types (including complex). The PLUS and TIMES operators are provided for both complex types, for 4 additional complex monoids. Sixteen monoids are predefined for four bitwise operators (BOR, BAND, BXOR, and BXNOR), each with four unsigned integer types (UINT8, UINT16, UINT32, and UINT64).

**NOTE:** The `GrB_TIMES_FP*` operators do not have a terminal value of zero, since they comply with the IEEE 754 standard, and `0*NaN` is not zero, but `NaN`. Technically, their terminal value is `NaN`, but this value is rare in practice and thus the terminal condition is not worth checking.

The next sections define the following methods for the `GrB_Monoid` object:

GraphBLAS function	purpose	Section
<code>GrB_Monoid_new</code>	create a user-defined monoid	<a href="#">6.6.1</a>
<code>GrB_Monoid_wait</code>	wait for a user-defined monoid	<a href="#">6.6.2</a>
<code>GxB_Monoid_terminal_new</code>	create a monoid that has a terminal value	<a href="#">6.6.3</a>
<code>GrB_Monoid_free</code>	free a monoid	<a href="#">6.6.4</a>
<code>GrB_get</code>	get properties of a monoid	<a href="#">10.8</a>
<code>GrB_set</code>	set the monoid name	<a href="#">10.8</a>

### 6.6.1 `GrB_Monoid_new`: create a monoid

```
GrB_Info GrB_Monoid_new          // create a monoid
(
    GrB_Monoid *monoid,          // handle of monoid to create
    GrB_BinaryOp op,             // binary operator of the monoid
    <type> identity               // identity value of the monoid
) ;
```

`GrB_Monoid_new` creates a monoid. The operator, `op`, must be an associative binary operator, either built-in or user-defined.

In the definition above, `<type>` is a place-holder for the specific type of the monoid. For built-in types, it is the C type corresponding to the built-in type (see Section [6.1](#)), such as `bool`, `int32_t`, `float`, or `double`. In this case, `identity` is a scalar value of the particular type, not a pointer. For user-defined types, `<type>` is `void *`, and thus `identity` is not a scalar itself but a `void *` pointer to a memory location containing the identity value of the user-defined operator, `op`.

If `op` is a built-in operator with a known identity value, then the `identity` parameter is ignored, and its known identity value is used instead. The `op` cannot be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

### 6.6.2 `GrB_Monoid_wait`: wait for a monoid

```
GrB_Info GrB_wait                // wait for a user-defined monoid
(
    GrB_Monoid monoid,           // monoid to wait for
    int mode                     // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

After creating a user-defined monoid, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing except to ensure that the `monoid` is valid.

### 6.6.3 GrB\_Monoid\_terminal\_new: create a monoid with terminal

```
GrB_Info GrB_Monoid_terminal_new    // create a monoid that has a terminal value
(
    GrB_Monoid *monoid,              // handle of monoid to create
    GrB_BinaryOp op,                 // binary operator of the monoid
    <type> identity,                  // identity value of the monoid
    <type> terminal                    // terminal value of the monoid
) ;
```

`GrB_Monoid_terminal_new` is identical to `GrB_Monoid_new`, except that it allows for the specification of a *terminal value*. The `<type>` of the terminal value is the same as the `identity` parameter; see Section 6.6.1 for details.

The terminal value of a monoid is the value  $z$  for which  $z = f(z, y)$  for any  $y$ , where  $z = f(x, y)$  is the binary operator of the monoid. This is also called the *annihilator*, but the term *terminal value* is used here. This is because all annihilators are terminal values, but a terminal value need not be an annihilator, as described in the MIN example below.

If the terminal value is encountered during computation, the rest of the computations can be skipped. This can greatly improve the performance of `GrB_reduce`, and matrix multiply in specific cases (when a dot product method is used). For example, using `GrB_reduce` to compute the sum of all entries in a `GrB_FP32` matrix with  $e$  entries takes  $O(e)$  time, since a monoid based on `GrB_PLUS_FP32` has no terminal value. By contrast, a reduction using `GrB_LOR` on a `GrB_BOOL` matrix can take as little as  $O(1)$  time, if a `true` value is found in the matrix very early.

Monoids based on the built-in `GrB_MIN_*` and `GrB_MAX_*` operators (for any type), the boolean `GrB_LOR`, and the boolean `GrB_LAND` operators all have terminal values. For example, the identity value of `GrB_LOR` is `false`, and its terminal value is `true`. When computing a reduction of a set of boolean values to a single value, once a `true` is seen, the computation can exit early since the result is now known.

If `op` is a built-in operator with known identity and terminal values, then the `identity` and `terminal` parameters are ignored, and its known identity and terminal values are used instead.

There may be cases in which the user application needs to use a non-standard terminal value for a built-in operator. For example, suppose the matrix has type `GrB_FP32`, but all values in the matrix are known to be non-negative. The annihilator value of MIN is `-INFINITY`, but this will never be seen. However, the computation could terminate when finding the value

zero. This is an example of using a terminal value that is not actually an annihilator, but it functions like one since the monoid will operate strictly on non-negative values.

In this case, a monoid created with `GrB_MIN_FP32` will not terminate early, because the identity and terminal inputs are ignored when using `GrB_Monoid_new` with a built-in operator as its input. To create a monoid that can terminate early, create a user-defined operator that computes the same thing as `GrB_MIN_FP32`, and then create a monoid based on this user-defined operator with a terminal value of zero and an identity of `+INFINITY`. The op cannot be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

#### 6.6.4 `GrB_Monoid_free`: free a monoid

```
GrB_Info GrB_free                // free a user-created monoid
(
    GrB_Monoid *monoid            // handle of monoid to free
) ;
```

`GrB_Monoid_frees` frees a monoid. Either usage:

```
GrB_Monoid_free (&monoid) ;
GrB_free (&monoid) ;
```

frees the `monoid` and sets `monoid` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `monoid == NULL` on input. It does nothing at all if passed a built-in monoid.

## 6.7 GraphBLAS semirings: GrB\_Semiring

A *semiring* defines all the operators required to define the multiplication of two sparse matrices in GraphBLAS,  $\mathbf{C} = \mathbf{AB}$ . The “add” operator is a commutative and associative monoid, and the binary “multiply” operator defines a function  $z = fmult(x, y)$  where the type of  $z$  matches the exactly with the monoid type. SuiteSparse:GraphBLAS includes 1,473 predefined built-in semirings. The next sections define the following methods for the GrB\_Semiring object:

GraphBLAS function	purpose	Section
GrB_Semiring_new	create a user-defined semiring	<a href="#">6.7.1</a>
GrB_Semiring_wait	wait for a user-defined semiring	<a href="#">6.7.2</a>
GrB_Semiring_free	free a semiring	<a href="#">6.7.3</a>
GrB_get	get properties of a semiring	<a href="#">10.9</a>
GrB_set	set the semiring name	<a href="#">10.9</a>

### 6.7.1 GrB\_Semiring\_new: create a semiring

```
GrB_Info GrB_Semiring_new          // create a semiring
(
    GrB_Semiring *semiring,         // handle of semiring to create
    GrB_Monoid add,                 // add monoid of the semiring
    GrB_BinaryOp multiply           // multiply operator of the semiring
) ;
```

GrB\_Semiring\_new creates a new semiring, with add being the additive monoid and multiply being the binary “multiply” operator. In addition to the standard error cases, the function returns GrB\_DOMAIN\_MISMATCH if the output (ztype) domain of multiply does not match the domain of the add monoid.

The v2.0 C API Specification for GraphBLAS includes 124 predefined semirings, with names of the form GrB\_add\_mult\_SEMIRING\_type, where add is the operator of the additive monoid, mult is the multiply operator, and type is the type of the input  $x$  to the multiply operator,  $f(x, y)$ . The name of the domain for the additive monoid does not appear in the name, since it always matches the type of the output of the mult operator. Twelve kinds of GrB\* semirings are available for all 10 real, non-boolean types: PLUS\_TIMES, PLUS\_MIN, MIN\_PLUS, MIN\_TIMES, MIN\_FIRST, MIN\_SECOND, MIN\_MAX, MAX\_PLUS, MAX\_TIMES, MAX\_FIRST, MAX\_SECOND, and

MAX\_MIN. Four semirings are for boolean types only: LOR\_LAND, LAND\_LOR, LXOR\_LAND, and LXXOR\_LOR.

SuiteSparse:GraphBLAS pre-defines 1,553 semirings from built-in types and operators, listed below. The naming convention is `GxB_add_mult_type`. The 124 `GrB*` semirings are a subset of the list below, included with two names: `GrB*` and `GxB*`. If the `GrB*` name is provided, its use is preferred, for portability to other GraphBLAS implementations.

- 1000 semirings with a multiplier  $T \times T \rightarrow T$  where  $T$  is any of the 10 non-Boolean, real types, from the complete cross product of:
  - 5 monoids (MIN, MAX, PLUS, TIMES, ANY)
  - 20 multiply operators (FIRST, SECOND, PAIR (same as ONEB), MIN, MAX, PLUS, MINUS, RMINUS, TIMES, DIV, RDIV, ISEQ, ISNE, ISGT, ISLT, ISGE, ISLE, LOR, LAND, LXOR).
  - 10 non-Boolean types,  $T$
- 300 semirings with a comparator  $T \times T \rightarrow \text{bool}$ , where  $T$  is non-Boolean and real, from the complete cross product of:
  - 5 Boolean monoids (LAND, LOR, LXOR, EQ, ANY)
  - 6 multiply operators (EQ, NE, GT, LT, GE, LE)
  - 10 non-Boolean types,  $T$
- 55 semirings with purely Boolean types,  $\text{bool} \times \text{bool} \rightarrow \text{bool}$ , from the complete cross product of:
  - 5 Boolean monoids (LAND, LOR, LXOR, EQ, ANY)
  - 11 multiply operators (FIRST, SECOND, PAIR (same as ONEB), LOR, LAND, LXOR, EQ, GT, LT, GE, LE)
- 54 complex semirings,  $Z \times Z \rightarrow Z$  where  $Z$  is `GxB_FC32` (single precision complex) or `GxB_FC64` (double precision complex):
  - 3 complex monoids (PLUS, TIMES, ANY)
  - 9 complex multiply operators (FIRST, SECOND, PAIR (same as ONEB), PLUS, MINUS, TIMES, DIV, RDIV, RMINUS)
  - 2 complex types,  $Z$

- 64 bitwise semirings,  $U \times U \rightarrow U$  where  $U$  is an unsigned integer.
  - 4 bitwise monoids (BOR, BAND, BXOR, BXNOR)
  - 4 bitwise multiply operators (the same list)
  - 4 unsigned integer types
- 80 index-based semirings,  $X \times X \rightarrow N$  where  $N$  is INT32 or INT64:
  - 5 monoids (MIN, MAX, PLUS, TIMES, ANY)
  - 8 index-based operators (FIRSTI, FIRSTI1, FIRSTJ, FIRSTJ1, SECONDI, SECONDI1, SECONDJ, SECONDJ1)
  - 2 integer types (INT32, INT64)

The multiply operator can be any a binary operator, including one created by `GxB_BinaryOp_new_IndexOp`.

### 6.7.2 GrB\_Semiring\_wait: wait for a semiring

```
GrB_Info GrB_wait          // wait for a user-defined semiring
(
    GrB_Semiring semiring,  // semiring to wait for
    int mode                // GrB_COMPLETE or GrB_MATERIALIZE
);
```

After creating a user-defined semiring, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing except to ensure that the `semiring` is valid.

### 6.7.3 GrB\_Semiring\_free: free a semiring

```
GrB_Info GrB_free          // free a user-created semiring
(
    GrB_Semiring *semiring  // handle of semiring to free
);
```

`GrB_Semiring_free` frees a semiring. Either usage:

```
GrB_Semiring_free (&semiring) ;
GrB_free (&semiring) ;
```

frees the `semiring` and sets `semiring` to NULL. It safely does nothing if passed a NULL handle, or if `semiring == NULL` on input. It does nothing at all if passed a built-in semiring.

## 6.8 GraphBLAS scalars: GrB\_Scalar

This section describes a set of methods that create, modify, query, and destroy a GraphBLAS scalar, `GrB_Scalar`:

GraphBLAS function	purpose	Section
<code>GrB_Scalar_new</code>	create a scalar	<a href="#">6.8.1</a>
<code>GrB_Scalar_wait</code>	wait for a scalar	<a href="#">6.8.2</a>
<code>GrB_Scalar_dup</code>	copy a scalar	<a href="#">6.8.3</a>
<code>GrB_Scalar_clear</code>	clear a scalar of its entry	<a href="#">6.8.4</a>
<code>GrB_Scalar_nvals</code>	return number of entries in a scalar	<a href="#">6.8.5</a>
<code>GrB_Scalar_setElement</code>	set the single entry of a scalar	<a href="#">6.8.6</a>
<code>GrB_Scalar_extractElement</code>	get the single entry from a scalar	<a href="#">6.8.7</a>
<code>GxB_Scalar_memoryUsage</code>	memory used by a scalar	<a href="#">6.8.8</a>
<code>GxB_Scalar_type</code>	type of a scalar	<a href="#">6.8.9</a>
<code>GrB_Scalar_free</code>	free a scalar	<a href="#">6.8.10</a>
<hr/>		
<code>GrB_get</code>	get properties of a scalar	<a href="#">10.12</a>
<code>GrB_set</code>	set properties of a scalar	<a href="#">10.12</a>

### 6.8.1 GrB\_Scalar\_new: create a scalar

```
GrB_Info GrB_Scalar_new    // create a new GrB_Scalar with no entry
(
    GrB_Scalar *s,          // handle of GrB_Scalar to create
    GrB_Type type           // type of GrB_Scalar to create
);
```

`GrB_Scalar_new` creates a new scalar with no entry in it, of the given type. This is analogous to MATLAB/Octave statement `s = sparse(0)`, except that GraphBLAS can create scalars any type. The pattern of the new scalar is empty.

### 6.8.2 GrB\_Scalar\_wait: wait for a scalar

```
GrB_Info GrB_wait          // wait for a scalar
(
    GrB_Scalar s,           // scalar to wait for
    int mode                // GrB_COMPLETE or GrB_MATERIALIZE
);
```

In non-blocking mode, the computations for a `GrB_Scalar` may be delayed. In this case, the scalar is not yet safe to use by multiple independent user threads. A user application may force completion of a scalar `s` via

`GrB_Scalar_wait(s,mode)`. With a mode of `GrB_MATERIALIZE`, all pending computations are finished, and afterwards different user threads may simultaneously call GraphBLAS operations that use the scalar `s` as an input parameter. See Section 10.2.2 if GraphBLAS is compiled without OpenMP.

### 6.8.3 `GrB_Scalar_dup`: copy a scalar

```
GrB_Info GrB_Scalar_dup    // make an exact copy of a GrB_Scalar
(
    GrB_Scalar *s,         // handle of output GrB_Scalar to create
    const GrB_Scalar t     // input GrB_Scalar to copy
);
```

`GrB_Scalar_dup` makes a deep copy of a scalar. In GraphBLAS, it is possible, and valid, to write the following:

```
GrB_Scalar t, s ;
GrB_Scalar_new (&t, GrB_FP64) ;
s = t ;           // s is a shallow copy of t
```

Then `s` and `t` can be used interchangeably. However, only a pointer reference is made, and modifying one of them modifies both, and freeing one of them leaves the other as a dangling handle that should not be used. If two different scalars are needed, then this should be used instead:

```
GrB_Scalar t, s ;
GrB_Scalar_new (&t, GrB_FP64) ;
GrB_Scalar_dup (&s, t) ;    // like s = t, but making a deep copy
```

Then `s` and `t` are two different scalars that currently have the same value, but they do not depend on each other. Modifying one has no effect on the other. The `GrB_NAME` is copied into the new scalar.

### 6.8.4 `GrB_Scalar_clear`: clear a scalar of its entry

```
GrB_Info GrB_Scalar_clear // clear a GrB_Scalar of its entry
(
    // type remains unchanged.
    GrB_Scalar s           // GrB_Scalar to clear
);
```

`GrB_Scalar_clear` clears the entry from a scalar. The pattern of `s` is empty, just as if it were created fresh with `GrB_Scalar_new`. Analogous with `s = sparse (0)` in MATLAB/Octave. The type of `s` does not change. Any pending updates to the scalar are discarded.

### 6.8.5 GrB\_Scalar\_nvals: return the number of entries in a scalar

```
GrB_Info GrB_Scalar_nvals    // get the number of entries in a GrB_Scalar
(
    GrB_Index *nvals,        // GrB_Scalar has nvals entries (0 or 1)
    const GrB_Scalar s      // GrB_Scalar to query
) ;
```

`GrB_Scalar_nvals` returns the number of entries in a scalar, which is either 0 or 1. Roughly analogous to `nvals = nnz(s)` in MATLAB/Octave, except that the implicit value in GraphBLAS need not be zero and `nnz` (short for “number of nonzeros”) in MATLAB is better described as “number of entries” in GraphBLAS.

### 6.8.6 GrB\_Scalar\_setElement: set the single entry of a scalar

```
GrB_Info GrB_Scalar_setElement    // s = x
(
    GrB_Scalar s,                // GrB_Scalar to modify
    <type> x                     // user scalar to assign to s
) ;
```

`GrB_Scalar_setElement` sets the single entry in a scalar, like `s = sparse(x)` in MATLAB notation. For further details of this function, see `GrB_Matrix_setElement` in Section 6.10.12. If an error occurs, `GrB_error(&err,s)` returns details about the error. The scalar `x` can be any non-opaque C scalar corresponding to a built-in type, or `void *` for a user-defined type. It cannot be a `GrB_Scalar`.

### 6.8.7 GrB\_Scalar\_extractElement: get the single entry from a scalar

```
GrB_Info GrB_Scalar_extractElement  // x = s
(
    <type> *x,                      // user scalar extracted
    const GrB_Scalar s              // GrB_Scalar to extract an entry from
) ;
```

`GrB_Scalar_extractElement` extracts the single entry from a sparse scalar, like `x = full(s)` in MATLAB. Further details of this method are discussed in Section 6.10.13, which discusses `GrB_Matrix_extractElement`. **NOTE:** if no entry is present in the scalar `s`, then `x` is not modified, and the return value of `GrB_Scalar_extractElement` is `GrB_NO_VALUE`.

### 6.8.8 GxB\_Scalar\_memoryUsage: memory used by a scalar

```
GrB_Info GxB_Scalar_memoryUsage  // return # of bytes used for a scalar
(
    size_t *size,                  // # of bytes used by the scalar s
    const GrB_Scalar s            // GrB_Scalar to query
) ;
```

Returns the memory space required for a scalar, in bytes. By default, any read-only components are not included in the total memory. This can be changed with via `GrB_set`; see Section 10.2.

### 6.8.9 GxB\_Scalar\_type: type of a scalar

```
GrB_Info GxB_Scalar_type  // get the type of a GrB_Scalar
(
    GrB_Type *type,         // returns the type of the GrB_Scalar
    const GrB_Scalar s      // GrB_Scalar to query
) ;
```

Returns the type of a scalar. See `GxB_Matrix_type` for details (Section 6.10.26).

#### 6.8.10 GrB\_Scalar\_free: free a scalar

```
GrB_Info GrB_free          // free a GrB_Scalar
(
    GrB_Scalar *s          // handle of GrB_Scalar to free
) ;
```

GrB\_Scalar\_free frees a scalar. Either usage:

```
GrB_Scalar_free (&s) ;
GrB_free (&s) ;
```

frees the scalar `s` and sets `s` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `s == NULL` on input. Any pending updates to the scalar are abandoned.

## 6.9 GraphBLAS vectors: GrB\_Vector

This section describes a set of methods that create, modify, query, and destroy a GraphBLAS sparse vector, `GrB_Vector`:

GraphBLAS function	purpose	Section
<code>GrB_Vector_new</code>	create a vector	<a href="#">6.9.1</a>
<code>GrB_Vector_wait</code>	wait for a vector	<a href="#">6.9.2</a>
<code>GrB_Vector_dup</code>	copy a vector	<a href="#">6.9.3</a>
<code>GrB_Vector_clear</code>	clear a vector of all entries	<a href="#">6.9.4</a>
<code>GrB_Vector_size</code>	size of a vector	<a href="#">6.9.5</a>
<code>GrB_Vector_nvals</code>	number of entries in a vector	<a href="#">6.9.6</a>
<code>GrB_Vector_build</code>	build a vector from tuples	<a href="#">6.9.7</a>
<code>GxB_Vector_build_Vector</code>	build a vector from tuples	<a href="#">6.9.8</a>
<code>GxB_Vector_build_Scalar</code>	build a vector from tuples	<a href="#">6.9.9</a>
<code>GxB_Vector_build_Scalar_Vector</code>	build a vector from tuples	<a href="#">6.9.10</a>
<code>GrB_Vector_setElement</code>	add an entry to a vector	<a href="#">6.9.11</a>
<code>GrB_Vector_extractElement</code>	get an entry from a vector	<a href="#">6.9.12</a>
<code>GxB_Vector_isStoredElement</code>	check if entry present in vector	<a href="#">6.9.13</a>
<code>GrB_Vector_removeElement</code>	remove an entry from a vector	<a href="#">6.9.14</a>
<code>GrB_Vector_extractTuples</code>	get all entries from a vector	<a href="#">6.9.15</a>
<code>GxB_Vector_extractTuples_Vector</code>	get all entries from a vector	<a href="#">6.9.16</a>
<code>GrB_Vector_resize</code>	resize a vector	<a href="#">6.9.17</a>
<code>GxB_Vector_diag</code>	extract a diagonal from a matrix	<a href="#">6.9.18</a>
<code>GxB_Vector_memoryUsage</code>	memory used by a vector	<a href="#">6.9.19</a>
<code>GxB_Vector_type</code>	type of the matrix	<a href="#">6.9.20</a>
<code>GrB_Vector_free</code>	free a vector	<a href="#">6.9.21</a>
<hr/>		
<code>GxB_Vector_serialize</code>	serialize a vector	<a href="#">6.11.1</a>
<code>GxB_Vector_deserialize</code>	deserialize a vector	<a href="#">6.11.2</a>
<hr/>		
<code>GxB_Vector_sort</code>	sort a vector	<a href="#">6.15.1</a>
<hr/>		
<code>GrB_get</code>	get properties of a vector	<a href="#">10.11</a>
<code>GrB_set</code>	set properties of a vector	<a href="#">10.11</a>

Refer to Section [6.11](#) for serialization/deserialization methods and to Section [6.15](#) for sorting methods.

### 6.9.1 GrB\_Vector\_new: create a vector

```
GrB_Info GrB_Vector_new      // create a new vector with no entries
(
    GrB_Vector *v,           // handle of vector to create
    GrB_Type type,           // type of vector to create
    GrB_Index n               // vector dimension is n-by-1
) ;
```

`GrB_Vector_new` creates a new  $n$ -by-1 sparse vector with no entries in it, of the given type. This is analogous to MATLAB/Octave statement `v = sparse (n,1)`, except that GraphBLAS can create sparse vectors any type. The pattern of the new vector is empty.

**SPEC:**  $n$  may be zero, as an extension to the specification.

### 6.9.2 GrB\_Vector\_wait: wait for a vector

```
GrB_Info GrB_wait            // wait for a vector
(
    GrB_Vector w,             // vector to wait for
    int mode                   // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

In non-blocking mode, the computations for a `GrB_Vector` may be delayed. In this case, the vector is not yet safe to use by multiple independent user threads. A user application may force completion of a vector `w` via `GrB_Vector_wait(w,mode)`. With a mode of `GrB_MATERIALIZE`, all pending computations are finished, and afterwards different user threads may simultaneously call GraphBLAS operations that use the vector `w` as an input parameter. See Section 10.2.2 if GraphBLAS is compiled without OpenMP.

### 6.9.3 GrB\_Vector\_dup: copy a vector

```
GrB_Info GrB_Vector_dup    // make an exact copy of a vector
(
    GrB_Vector *w,          // handle of output vector to create
    const GrB_Vector u      // input vector to copy
) ;
```

`GrB_Vector_dup` makes a deep copy of a sparse vector. In GraphBLAS, it is possible, and valid, to write the following:

```
GrB_Vector u, w ;
GrB_Vector_new (&u, GrB_FP64, n) ;
w = u ;          // w is a shallow copy of u
```

Then `w` and `u` can be used interchangeably. However, only a pointer reference is made, and modifying one of them modifies both, and freeing one of them leaves the other as a dangling handle that should not be used. If two different vectors are needed, then this should be used instead:

```
GrB_Vector u, w ;
GrB_Vector_new (&u, GrB_FP64, n) ;
GrB_Vector_dup (&w, u) ;    // like w = u, but making a deep copy
```

Then `w` and `u` are two different vectors that currently have the same set of values, but they do not depend on each other. Modifying one has no effect on the other. The `GrB_NAME` is copied into the new vector.

### 6.9.4 GrB\_Vector\_clear: clear a vector of all entries

```
GrB_Info GrB_Vector_clear  // clear a vector of all entries;
(
    // type and dimension remain unchanged.
    GrB_Vector v            // vector to clear
) ;
```

`GrB_Vector_clear` clears all entries from a vector. All values `v(i)` are now equal to the implicit value, depending on what semiring ring is used to perform computations on the vector. The pattern of `v` is empty, just as if it were created fresh with `GrB_Vector_new`. Analogous with `v(:) = sparse(0)` in MATLAB. The type and dimension of `v` do not change. Any pending updates to the vector are discarded.

### 6.9.5 GrB\_Vector\_size: return the size of a vector

```
GrB_Info GrB_Vector_size    // get the dimension of a vector
(
    GrB_Index *n,           // vector dimension is n-by-1
    const GrB_Vector v      // vector to query
) ;
```

`GrB_Vector_size` returns the size of a vector (the number of rows). Analogous to `n = length(v)` or `n = size(v,1)` in MATLAB.

### 6.9.6 GrB\_Vector\_nvals: return the number of entries in a vector

```
GrB_Info GrB_Vector_nvals   // get the number of entries in a vector
(
    GrB_Index *nvals,       // vector has nvals entries
    const GrB_Vector v      // vector to query
) ;
```

`GrB_Vector_nvals` returns the number of entries in a vector. Roughly analogous to `nvals = nnz(v)` in MATLAB, except that the implicit value in GraphBLAS need not be zero and `nnz` (short for “number of nonzeros”) in MATLAB is better described as “number of entries” in GraphBLAS.

### 6.9.7 GrB\_Vector\_build: build a vector from a set of tuples

```
GrB_Info GrB_Vector_build   // build a vector from (I,X) tuples
(
    GrB_Vector w,           // vector to build
    const GrB_Index *I,     // array of row indices of tuples
    const <type> *X,        // array of values of tuples
    GrB_Index nvals,        // number of tuples
    const GrB_BinaryOp dup   // binary function to assemble duplicates
) ;
```

`GrB_Vector_build` constructs a sparse vector `w` from a set of tuples, `I` and `X`, each of length `nvals`. The vector `w` must have already been initialized with `GrB_Vector_new`, and it must have no entries in it before calling `GrB_Vector_build`. This function is just like `GrB_Matrix_build` (see Section 6.10.8), except that it builds a sparse vector instead of a sparse matrix. For a description of what `GrB_Vector_build` does, refer to `GrB_Matrix_build`.

For a vector, the list of column indices `J` in `GrB_Matrix_build` is implicitly a vector of length `nvals` all equal to zero. Otherwise the methods are identical.

If `dup` is `NULL`, any duplicates result in an error. If `dup` is the special binary operator `GxB_IGNORE_DUP`, then any duplicates are ignored. If duplicates appear, the last one in the list of tuples is taken and the prior ones ignored. This is not an error. The `dup` operator cannot be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

**SPEC:** Results are defined even if `dup` is non-associative and/or non-commutative.

#### 6.9.8 `GrB_Vector_build_Vector`: build a vector from a set of tuples

```
GrB_Info GrB_Vector_build      // build a vector from (I,X) tuples
(
    GrB_Vector w,              // vector to build
    const GrB_Vector I_vector, // row indices
    const GrB_Vector X_vector, // values
    const GrB_BinaryOp dup,    // binary function to assemble duplicates
    const GrB_Descriptor desc
);
```

`GxB_Vector_build_Vector` is identical to `GrB_Vector_build`, except that the inputs `I` and `X` are `GrB_Vector` objects, each with `nvals` entries. The interpretation of `I_vector` and `X_vector` are controlled by descriptor settings `GxB_ROWINDEX_LIST` and `GxB_VALUE_LIST`, respectively. The method can use either the indices or values of each of the input vectors; the default is to use the values. See Section 6.16.4 for details.

#### 6.9.9 `GxB_Vector_build_Scalar`: build a vector from a set of tuples

```
GrB_Info GrB_Vector_build      // build a vector from (I,scalar) tuples
(
    GrB_Vector w,              // vector to build
    const GrB_Index *I,        // array of row indices of tuples
    GrB_Scalar scalar,         // value for all tuples
    GrB_Index nvals            // number of tuples
);
```

`GxB_Vector_build_Scalar` constructs a sparse vector `w` from a set of tuples defined by the index array `I` of length `nvals`, and a scalar. The

scalar is the value of all of the tuples. Unlike `GrB_Vector_build`, there is no `dup` operator to handle duplicate entries. Instead, any duplicates are silently ignored (if the number of duplicates is desired, simply compare the input `nvals` with the value returned by `GrB_Vector_nvals` after the vector is constructed). All entries in the sparsity pattern of `w` are identical, and equal to the input scalar value.

#### 6.9.10 `GxB_Vector_build_Scalar_Vector`: build a vector from a set of tuples

```
GrB_Info GrB_Vector_build      // build a vector from (I,scalar) tuples
(
    GrB_Vector w,              // vector to build
    const GrB_Vector I_vector, // row indices
    const GrB_Scalar scalar,   // value for all tuples
    const GrB_Descriptor desc
) ;
```

`GxB_Vector_build_Scalar_Vector` is identical to `GxB_Vector_build_Scalar`, except that the inputs `I` and `X` are `GrB_Vector` objects, each with `nvals` entries. The interpretation of `I_vector` is controlled by the descriptor setting `GxB_ROWINDEX_LIST`. The method can use either the indices or values of the `I_input` vector; the default is to use the values. See Section 6.16.4 for details.

#### 6.9.11 `GrB_Vector_setElement`: add an entry to a vector

```
GrB_Info GrB_Vector_setElement // w(i) = x
(
    GrB_Vector w,              // vector to modify
    <type> x,                  // scalar to assign to w(i)
    GrB_Index i                // index
) ;
```

`GrB_Vector_setElement` sets a single entry in a vector,  $w(i) = x$ . The operation is exactly like setting a single entry in an  $n$ -by-1 matrix,  $A(i,0) = x$ , where the column index for a vector is implicitly  $j=0$ . For further details of this function, see `GrB_Matrix_setElement` in Section 6.10.12. If an error occurs, `GrB_error(&err,w)` returns details about the error.

### 6.9.12 GrB\_Vector\_extractElement: get an entry from a vector

```
GrB_Info GrB_Vector_extractElement  // x = v(i)
(
    <type> *x,                // scalar extracted (non-opaque, C scalar)
    const GrB_Vector v,        // vector to extract an entry from
    GrB_Index i                // index
) ;

GrB_Info GrB_Vector_extractElement  // x = v(i)
(
    GrB_Scalar x,              // GrB_Scalar extracted
    const GrB_Vector v,        // vector to extract an entry from
    GrB_Index i                // index
) ;
```

`GrB_Vector_extractElement` extracts a single entry from a vector,  $x = v(i)$ . The method is identical to extracting a single entry  $x = A(i,0)$  from an  $n$ -by-1 matrix; see Section [6.10.13](#).

### 6.9.13 GxB\_Vector\_isStoredElement: check if entry present in vector

```
GrB_Info GxB_Vector_isStoredElement
(
    const GrB_Vector v,        // check presence of entry v(i)
    GrB_Index i                // index
) ;
```

`GxB_Vector_isStoredElement` checks if a single entry  $v(i)$  is present, returning `GrB_SUCCESS` if the entry is present or `GrB_NO_VALUE` otherwise. The value of  $v(i)$  is not returned. See also Section [6.10.14](#).

### 6.9.14 GrB\_Vector\_removeElement: remove an entry from a vector

```
GrB_Info GrB_Vector_removeElement
(
    GrB_Vector w,              // vector to remove an entry from
    GrB_Index i                // index
) ;
```

`GrB_Vector_removeElement` removes a single entry  $w(i)$  from a vector. If no entry is present at  $w(i)$ , then the vector is not modified. If an error occurs, `GrB_error(&err,w)` returns details about the error.

### 6.9.15 GrB\_Vector\_extractTuples: get all entries from a vector

```
GrB_Info GrB_Vector_extractTuples          // [I,~,X] = find (v)
(
    GrB_Index *I,                          // array for returning row indices of tuples
    <type> *X,                             // array for returning values of tuples
    GrB_Index *nvals,                      // I, X size on input; # tuples on output
    const GrB_Vector v                    // vector to extract tuples from
) ;
```

`GrB_Vector_extractTuples` extracts all tuples from a sparse vector, analogous to `[I,~,X] = find(v)` in MATLAB/Octave. This function is identical to its `GrB_Matrix_extractTuples` counterpart, except that the array of column indices `J` does not appear in this function. Refer to Section 6.10.16 where further details of this function are described.

### 6.9.16 GxB\_Vector\_extractTuples\_Vector: get all entries from a vector

```
GrB_Info GrB_Vector_extractTuples          // [I,~,X] = find (v)
(
    GrB_Vector I_vector,                  // row indices
    GrB_Vector X_vector,                  // values
    const GrB_Vector V,                  // vectors to extract tuples from
    const GrB_Descriptor desc             // currently unused; for future expansion
) ;
```

`GxB_Vector_extractTuples_Vector` is identical to `GrB_Vector_extractTuples` except that its two outputs are `GrB_Vector` objects. The vectors `I_vector` and `X_vector` objects must exist on input. On output, any prior content is erased and their type, dimensions, and values are revised to contain dense vectors of length `nvals`.

### 6.9.17 GrB\_Vector\_resize: resize a vector

```
GrB_Info GrB_Vector_resize      // change the size of a vector
(
    GrB_Vector u,                // vector to modify
    GrB_Index nrow_new           // new number of rows in vector
) ;
```

`GrB_Vector_resize` changes the size of a vector. If the dimension decreases, entries that fall outside the resized vector are deleted.

### 6.9.18 GxB\_Vector\_diag: extract a diagonal from a matrix

```
GrB_Info GxB_Vector_diag        // extract a diagonal from a matrix
(
    GrB_Vector v,                // output vector
    const GrB_Matrix A,          // input matrix
    int64_t k,                   // diagonal index
    const GrB_Descriptor desc     // unused, except threading control
) ;
```

`GxB_Vector_diag` extracts a vector  $v$  from an input matrix  $A$ , which may be rectangular. If  $k = 0$ , the main diagonal of  $A$  is extracted;  $k > 0$  denotes diagonals above the main diagonal of  $A$ , and  $k < 0$  denotes diagonals below the main diagonal of  $A$ . Let  $A$  have dimension  $m$ -by- $n$ . If  $k$  is in the range  $0$  to  $n - 1$ , then  $v$  has length  $\min(m, n - k)$ . If  $k$  is negative and in the range  $-1$  to  $-m + 1$ , then  $v$  has length  $\min(m + k, n)$ . If  $k$  is outside these ranges,  $v$  has length  $0$  (this is not an error). This function computes the same thing as the MATLAB/Octave statement `v=diag(A,k)` when  $A$  is a matrix, except that `GxB_Vector_diag` can also do typecasting.

The vector  $v$  must already exist on input, and `GrB_Vector_size (&len,v)` must return `len = 0` if  $k \geq n$  or  $k \leq -m$ , `len =  $\min(m, n - k)$`  if  $k$  is in the range  $0$  to  $n - 1$ , and `len =  $\min(m + k, n)$`  if  $k$  is in the range  $-1$  to  $-m + 1$ . Any existing entries in  $v$  are discarded. The type of  $v$  is preserved, so that if the type of  $A$  and  $v$  differ, the entries are typecasted into the type of  $v$ . Any settings made to  $v$  by `GrB_set` (bitmap switch and sparsity control) are unchanged.

### 6.9.19 GxB\_Vector\_memoryUsage: memory used by a vector

```
GrB_Info GxB_Vector_memoryUsage // return # of bytes used for a vector
(
    size_t *size,           // # of bytes used by the vector v
    const GrB_Vector v      // vector to query
) ;
```

Returns the memory space required for a vector, in bytes. By default, any read-only components are not included in the total memory. This can be changed with via `GrB_set`; see Section [10.2](#).

### 6.9.20 GxB\_Vector\_type: type of a vector

```
GrB_Info GxB_Vector_type // get the type of a vector
(
    GrB_Type *type,        // returns the type of the vector
    const GrB_Vector v     // vector to query
) ;
```

Returns the type of a vector. See `GxB_Matrix_type` for details (Section [6.10.26](#)).

### 6.9.21 GrB\_Vector\_free: free a vector

```
GrB_Info GrB_free // free a vector
(
    GrB_Vector *v      // handle of vector to free
) ;
```

`GrB_Vector_free` frees a vector. Either usage:

```
GrB_Vector_free (&v) ;
GrB_free (&v) ;
```

frees the vector `v` and sets `v` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `v == NULL` on input. Any pending updates to the vector are abandoned.

## 6.10 GraphBLAS matrices: GrB\_Matrix

This section describes a set of methods that create, modify, query, and destroy a GraphBLAS sparse matrix, `GrB_Matrix`:

GraphBLAS function	purpose	Section
<code>GrB_Matrix_new</code>	create a matrix	<a href="#">6.10.1</a>
<code>GrB_Matrix_wait</code>	wait for a matrix	<a href="#">6.10.2</a>
<code>GrB_Matrix_dup</code>	copy a matrix	<a href="#">6.10.3</a>
<code>GrB_Matrix_clear</code>	clear a matrix of all entries	<a href="#">6.10.4</a>
<code>GrB_Matrix_nrows</code>	number of rows of a matrix	<a href="#">6.10.5</a>
<code>GrB_Matrix_ncols</code>	number of columns of a matrix	<a href="#">6.10.6</a>
<code>GrB_Matrix_nvals</code>	number of entries in a matrix	<a href="#">6.10.7</a>
<code>GrB_Matrix_build</code>	build a matrix from tuples	<a href="#">6.10.8</a>
<code>GxB_Matrix_build_Vector</code>	build a matrix from tuples	<a href="#">6.10.9</a>
<code>GxB_Matrix_build_Scalar</code>	build a matrix from tuples	<a href="#">6.10.10</a>
<code>GxB_Matrix_build_Scalar_Vector</code>	build a matrix from tuples	<a href="#">6.10.11</a>
<code>GrB_Matrix_setElement</code>	add an entry to a matrix	<a href="#">6.10.12</a>
<code>GrB_Matrix_extractElement</code>	get an entry from a matrix	<a href="#">6.10.13</a>
<code>GxB_Matrix_isStoredElement</code>	check if entry present in matrix	<a href="#">6.10.14</a>
<code>GrB_Matrix_removeElement</code>	remove an entry from a matrix	<a href="#">6.10.15</a>
<code>GrB_Matrix_extractTuples</code>	get all entries from a matrix	<a href="#">6.10.16</a>
<code>GxB_Matrix_extractTuples_Vector</code>	get all entries from a matrix	<a href="#">6.10.17</a>
<code>GrB_Matrix_resize</code>	resize a matrix	<a href="#">6.10.18</a>
<code>GxB_Matrix_reshape</code>	reshape a matrix	<a href="#">6.10.19</a>
<code>GxB_Matrix_reshapeDup</code>	reshape a matrix	<a href="#">6.10.20</a>
<code>GxB_Matrix_concat</code>	concatenate matrices	<a href="#">6.10.21</a>
<code>GxB_Matrix_split</code>	split a matrix into matrices	<a href="#">6.10.22</a>
<code>GrB_Matrix_diag</code>	diagonal matrix from vector	<a href="#">6.10.23</a>
<code>GxB_Matrix_diag</code>	diagonal matrix from vector	<a href="#">6.10.24</a>
<code>GxB_Matrix_memoryUsage</code>	memory used by a matrix	<a href="#">6.10.25</a>
<code>GxB_Matrix_type</code>	type of the matrix	<a href="#">6.10.26</a>
<code>GrB_Matrix_free</code>	free a matrix	<a href="#">6.10.27</a>
<code>GrB_Matrix_serializeSize</code>	return size of serialized matrix	<a href="#">6.11.3</a>
<code>GrB_Matrix_serialize</code>	serialize a matrix	<a href="#">6.11.4</a>
<code>GxB_Matrix_serialize</code>	serialize a matrix	<a href="#">6.11.5</a>
<code>GrB_Matrix_deserialize</code>	deserialize a matrix	<a href="#">6.11.6</a>
<code>GxB_Matrix_deserialize</code>	deserialize a matrix	<a href="#">6.11.7</a>
<code>GrB_get</code>	get properties of a matrix	<a href="#">10.10</a>
<code>GrB_set</code>	set properties of a matrix	<a href="#">10.10</a>

GraphBLAS function	purpose	Section
<code>GrB_Matrix_import</code>	import in various formats	<a href="#">6.14.1</a>
<code>GrB_Matrix_export</code>	export in various formats	<a href="#">6.14.2</a>
<code>GrB_Matrix_exportSize</code>	array sizes for export	<a href="#">6.14.3</a>
<code>GrB_Matrix_exportHint</code>	hint best export format	<a href="#">6.14.4</a>
<code>GxB_Matrix_sort</code>	sort a matrix	<a href="#">6.15.2</a>

Refer to Section [6.11](#) for serialization/deserialization methods, Section [6.14](#) for GrB import/export methods, Section [6.15](#) for sorting methods, and Section [10.10](#) for get/set methods.

### 6.10.1 GrB\_Matrix\_new: create a matrix

```
GrB_Info GrB_Matrix_new      // create a new matrix with no entries
(
    GrB_Matrix *A,           // handle of matrix to create
    GrB_Type type,           // type of matrix to create
    GrB_Index nrows,         // matrix dimension is nrows-by-ncols
    GrB_Index ncols
) ;
```

`GrB_Matrix_new` creates a new `nrows-by-ncols` sparse matrix with no entries in it, of the given type. This is analogous to the MATLAB statement `A = sparse (nrows, ncols)`, except that GraphBLAS can create sparse matrices of any type.

By default, matrices of size `nrows-by-1` are held by column, regardless of the global setting controlled by `GrB_set (GrB_GLOBAL, ..., GrB_STORAGE_ORIENTATION_HINT)`, for any value of `nrows`. Matrices of size `1-by-ncols` with `ncols` not equal to 1 are held by row, regardless of this global setting. The global setting only affects matrices with both `m > 1` and `n > 1`. Empty matrices (`0-by-0`) are also controlled by the global setting.

Once a matrix is created, its format (by-row or by-column) can be arbitrarily changed with `GrB_set (A, fmt, GrB_STORAGE_ORIENTATION_HINT)` with `fmt` equal to `GrB_COLMAJOR` or `GrB_ROWMAJOR`.

**SPEC:** `nrows` and/or `ncols` may be zero. as an extension to the specification.

### 6.10.2 GrB\_Matrix\_wait: wait for a matrix

```
GrB_Info GrB_wait          // wait for a matrix
(
    GrB_Matrix C,          // matrix to wait for
    int mode               // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

In non-blocking mode, the computations for a `GrB_Matrix` may be delayed. In this case, the matrix is not yet safe to use by multiple independent user threads. A user application may force completion of a matrix `C` via `GrB_Matrix_wait(C,mode)`. With a mode of `GrB_MATERIALIZE`, all pending computations are finished, and afterwards different user threads may simultaneously call GraphBLAS operations that use the matrix `C` as an input parameter. See Section 10.2.2 if GraphBLAS is compiled without OpenMP.

### 6.10.3 GrB\_Matrix\_dup: copy a matrix

```
GrB_Info GrB_Matrix_dup    // make an exact copy of a matrix
(
    GrB_Matrix *C,          // handle of output matrix to create
    const GrB_Matrix A      // input matrix to copy
) ;
```

`GrB_Matrix_dup` makes a deep copy of a sparse matrix. In GraphBLAS, it is possible, and valid, to write the following:

```
GrB_Matrix A, C ;
GrB_Matrix_new (&A, GrB_FP64, n) ;
C = A ;          // C is a shallow copy of A
```

Then `C` and `A` can be used interchangeably. However, only a pointer reference is made, and modifying one of them modifies both, and freeing one of them leaves the other as a dangling handle that should not be used. If two different matrices are needed, then this should be used instead:

```
GrB_Matrix A, C ;
GrB_Matrix_new (&A, GrB_FP64, n) ;
GrB_Matrix_dup (&C, A) ;          // like C = A, but making a deep copy
```

Then `C` and `A` are two different matrices that currently have the same set of values, but they do not depend on each other. Modifying one has no effect on the other. The `GrB_NAME` is copied into the new matrix.

#### 6.10.4 GrB\_Matrix\_clear: clear a matrix of all entries

```
GrB_Info GrB_Matrix_clear    // clear a matrix of all entries;
(
    GrB_Matrix A              // type and dimensions remain unchanged
                              // matrix to clear
) ;
```

`GrB_Matrix_clear` clears all entries from a matrix. All values  $A(i,j)$  are now equal to the implicit value, depending on what semiring ring is used to perform computations on the matrix. The pattern of  $A$  is empty, just as if it were created fresh with `GrB_Matrix_new`. Analogous with  $A(:, :) = 0$  in MATLAB. The type and dimensions of  $A$  do not change. Any pending updates to the matrix are discarded.

#### 6.10.5 GrB\_Matrix\_nrows: return the number of rows of a matrix

```
GrB_Info GrB_Matrix_nrows    // get the number of rows of a matrix
(
    GrB_Index *nrows,         // matrix has nrows rows
    const GrB_Matrix A        // matrix to query
) ;
```

`GrB_Matrix_nrows` returns the number of rows of a matrix (`nrows=size(A,1)` in MATLAB).

#### 6.10.6 GrB\_Matrix\_ncols: return the number of columns of a matrix

```
GrB_Info GrB_Matrix_ncols    // get the number of columns of a matrix
(
    GrB_Index *ncols,         // matrix has ncols columns
    const GrB_Matrix A        // matrix to query
) ;
```

`GrB_Matrix_ncols` returns the number of columns of a matrix (`ncols=size(A,2)` in MATLAB).

### 6.10.7 GrB\_Matrix\_nvals: return the number of entries in a matrix

```
GrB_Info GrB_Matrix_nvals    // get the number of entries in a matrix
(
    GrB_Index *nvals,        // matrix has nvals entries
    const GrB_Matrix A       // matrix to query
) ;
```

`GrB_Matrix_nvals` returns the number of entries in a matrix. Roughly analogous to `nvals = nnz(A)` in MATLAB, except that the implicit value in GraphBLAS need not be zero and `nnz` (short for “number of nonzeros”) in MATLAB is better described as “number of entries” in GraphBLAS.

### 6.10.8 GrB\_Matrix\_build: build a matrix from a set of tuples

```
GrB_Info GrB_Matrix_build    // build a matrix from (I,J,X) tuples
(
    GrB_Matrix C,             // matrix to build
    const GrB_Index *I,       // array of row indices of tuples
    const GrB_Index *J,       // array of column indices of tuples
    const <type> *X,          // array of values of tuples
    GrB_Index nvals,          // number of tuples
    const GrB_BinaryOp dup     // binary function to assemble duplicates
) ;
```

`GrB_Matrix_build` constructs a sparse matrix `C` from a set of tuples, `I`, `J`, and `X`, each of length `nvals`. The matrix `C` must have already been initialized with `GrB_Matrix_new`, and it must have no entries in it before calling `GrB_Matrix_build`. Thus the dimensions and type of `C` are not changed by this function, but are inherited from the prior call to `GrB_Matrix_new` or `GrB_matrix_dup`.

An error is returned (`GrB_INDEX_OUT_OF_BOUNDS`) if any row index in `I` is greater than or equal to the number of rows of `C`, or if any column index in `J` is greater than or equal to the number of columns of `C`.

Any duplicate entries with identical indices are assembled using the binary `dup` operator provided on input. All three types (`x`, `y`, `z` for `z=dup(x,y)`) must be identical. The types of `dup`, `C` and `X` must all be compatible. See Section 2.4 regarding typecasting and compatibility. The values in `X` are type-casted, if needed, into the type of `dup`. Duplicates are then assembled into a matrix `T` of the same type as `dup`, using `T(i,j) = dup (T (i,j), X (k))`.

After  $T$  is constructed, it is typecasted into the result  $C$ . That is, typecasting does not occur at the same time as the assembly of duplicates.

If  $\text{dup}$  is `NULL`, any duplicates result in an error. If  $\text{dup}$  is the special binary operator `GxB_IGNORE_DUP`, then any duplicates are ignored. If duplicates appear, the last one in the list of tuples is taken and the prior ones ignored. This is not an error.

**SPEC:** As an extension to the specification, results are defined even if  $\text{dup}$  is non-associative and/or non-commutative.

The GraphBLAS API requires  $\text{dup}$  to be associative so that entries can be assembled in any order, and states that the result is undefined if  $\text{dup}$  is not associative. However, SuiteSparse:GraphBLAS guarantees a well-defined order of assembly. Entries in the tuples  $[I, J, X]$  are first sorted in increasing order of row and column index, with ties broken by the position of the tuple in the  $[I, J, X]$  list. If duplicates appear, they are assembled in the order they appear in the  $[I, J, X]$  input. That is, if the same indices  $i$  and  $j$  appear in positions  $k1$ ,  $k2$ ,  $k3$ , and  $k4$  in  $[I, J, X]$ , where  $k1 < k2 < k3 < k4$ , then the following operations will occur in order:

```
T (i,j) = X (k1) ;
T (i,j) = dup (T (i,j), X (k2)) ;
T (i,j) = dup (T (i,j), X (k3)) ;
T (i,j) = dup (T (i,j), X (k4)) ;
```

This is a well-defined order but the user should not depend upon it when using other GraphBLAS implementations since the GraphBLAS API does not require this ordering.

However, SuiteSparse:GraphBLAS guarantees this ordering, even when it compute the result in parallel. With this well-defined order, several operators become very useful. In particular, the **SECOND** operator results in the last tuple overwriting the earlier ones. The **FIRST** operator means the value of the first tuple is used and the others are discarded.

The acronym  $\text{dup}$  is used here for the name of binary function used for assembling duplicates, but this should not be confused with the `_dup` suffix in the name of the function `GrB_Matrix_dup`. The latter function does not apply any operator at all, nor any typecasting, but simply makes a pure deep copy of a matrix.

The parameter  $X$  is a pointer to any C equivalent built-in type, or a `void *` pointer. The `GrB_Matrix_build` function uses the `_Generic` feature

of C11 to detect the type of pointer passed as the parameter `X`. If `X` is a pointer to a built-in type, then the function can do the right typecasting. If `X` is a `void *` pointer, then it can only assume `X` to be a pointer to a user-defined type that is the same user-defined type of `C` and `dup`. This function has no way of checking this condition that the `void * X` pointer points to an array of the correct user-defined type, so behavior is undefined if the user breaks this condition.

The `GrB_Matrix_build` method is analogous to `C = sparse (I,J,X)` in MATLAB, with several important extensions that go beyond that which MATLAB can do. In particular, the MATLAB `sparse` function only provides one option for assembling duplicates (summation), and it can only build double, double complex, and logical sparse matrices. The `dup` operator cannot be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

#### 6.10.9 GxB\_Matrix\_build\_Vector: build a matrix from a set of tuples

```
GrB_Info GrB_Matrix_build          // build a matrix from (I,J,X) tuples
(
    GrB_Matrix C,                  // matrix to build
    const GrB_Vector I_vector,     // row indices
    const GrB_Vector J_vector,     // col indices
    const GrB_Vector X_vector,     // values
    const GrB_BinaryOp dup,        // binary function to assemble duplicates
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_build_Vector` is identical to `GrB_Matrix_build`, except that the inputs `I`, `J`, and `X` are `GrB_Vector` objects, each with `nvals` entries. The interpretation of `I_vector`, `J_vector`, and `X_vector` are controlled by descriptor settings `GxB_ROWINDEX_LIST`, `GxB_COLINDEX_LIST`, and `GxB_VALUE_LIST`, respectively. The method can use either the indices or values of each of the input vectors; the default is to use the values. See Section 6.16.4 for details.

#### 6.10.10 GxB\_Matrix\_build\_Scalar: build a matrix from a set of tuples

```
GrB_Info GrB_Matrix_build          // build a matrix from (I,J,scalar) tuples
(
    GrB_Matrix C,                  // matrix to build
    const GrB_Index *I,            // array of row indices of tuples
    const GrB_Index *J,            // array of column indices of tuples
    GrB_Scalar scalar,             // value for all tuples
    GrB_Index nvals                // number of tuples
) ;
```

`GxB_Matrix_build_Scalar` constructs a sparse matrix `C` from a set of tuples defined the index arrays `I` and `J` of length `nvals`, and a scalar. The scalar is the value of all of the tuples. Unlike `GrB_Matrix_build`, there is no `dup` operator to handle duplicate entries. Instead, any duplicates are silently ignored (if the number of duplicates is desired, simply compare the input `nvals` with the value returned by `GrB_Vector_nvals` after the matrix is constructed). All entries in the sparsity pattern of `C` are identical, and equal to the input scalar value.

#### 6.10.11 GxB\_Matrix\_build\_Scalar\_Vector: build a matrix from a set of tuples

```
GrB_Info GrB_Matrix_build          // build a matrix from (I,J,scalar) tuples
(
    GrB_Matrix C,                  // matrix to build
    const GrB_Vector I_vector,     // row indices
    const GrB_Vector J_vector,     // col indices
    GrB_Scalar scalar,             // value for all tuples
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_build_Scalar_Vector` is identical to `GxB_Matrix_build_Scalar`, except that the inputs `I`, `J`, and `X` are `GrB_Vector` objects, each with `nvals` entries. The interpretation of `I_vector` and `J_vector` are controlled by descriptor settings `GxB_ROWINDEX_LIST` and `GxB_VALUE_LIST`, respectively. The method can use either the indices or values of the `I_input` and `J_vector` vectors; the default is to use the values. See Section [6.16.4](#) for details.

### 6.10.12 GrB\_Matrix\_setElement: add an entry to a matrix

```
GrB_Info GrB_Matrix_setElement      // C (i,j) = x
(
    GrB_Matrix C,                    // matrix to modify
    <type> x,                        // scalar to assign to C(i,j)
    GrB_Index i,                     // row index
    GrB_Index j                       // column index
) ;
```

`GrB_Matrix_setElement` sets a single entry in a matrix,  $C(i,j)=x$ . If the entry is already present in the pattern of  $C$ , it is overwritten with the new value. If the entry is not present, it is added to  $C$ . In either case, no entry is ever deleted by this function. Passing in a value of  $x=0$  simply creates an explicit entry at position  $(i,j)$  whose value is zero, even if the implicit value is assumed to be zero.

An error is returned (`GrB_INVALID_INDEX`) if the row index  $i$  is greater than or equal to the number of rows of  $C$ , or if the column index  $j$  is greater than or equal to the number of columns of  $C$ . Note that this error code differs from the same kind of condition in `GrB_Matrix_build`, which returns `GrB_INDEX_OUT_OF_BOUNDS`. This is because `GrB_INVALID_INDEX` is an API error, and is caught immediately even in non-blocking mode, whereas `GrB_INDEX_OUT_OF_BOUNDS` is an execution error whose detection may wait until the computation completes sometime later.

The scalar  $x$  is typecasted into the type of  $C$ . Any value can be passed to this function and its type will be detected, via the `_Generic` feature of C11. For a user-defined type,  $x$  is a `void *` pointer that points to a memory space holding a single entry of this user-defined type. This user-defined type must exactly match the user-defined type of  $C$  since no typecasting is done between user-defined types. If  $x$  is a `GrB_Scalar` and contains no entry, then the entry  $C(i,j)$  is removed (if it exists). The action taken is identical to `GrB_Matrix_removeElement(C,i,j)` in this case.

**Performance considerations:** SuiteSparse:GraphBLAS exploits the non-blocking mode to greatly improve the performance of this method. Refer to the example shown in Section 2.2. If the entry exists in the pattern already, it is updated right away and the work is not left pending. Otherwise, it is placed in a list of pending updates, and the later on the updates are done all at once, using the same algorithm used for `GrB_Matrix_build`. In other words, `setElement` in SuiteSparse:GraphBLAS builds its own internal list of

tuples `[I,J,X]`, and then calls `GrB_Matrix_build` whenever the matrix is needed in another computation, or whenever `GrB_Matrix_wait` is called.

As a result, if calls to `setElement` are mixed with calls to most other methods and operations (even `extractElement`) then the pending updates are assembled right away, which will be slow. Performance will be good if many `setElement` updates are left pending, and performance will be poor if the updates are assembled frequently.

A few methods and operations can be intermixed with `setElement`, in particular, some forms of the `GrB_assign` and `GxB_subassign` operations are compatible with the pending updates from `setElement`. Section 12.11 gives more details on which `GxB_subassign` and `GrB_assign` operations can be interleaved with calls to `setElement` without forcing updates to be assembled. Other methods that do not access the existing entries may also be done without forcing the updates to be assembled, namely `GrB_Matrix_clear` (which erases all pending updates), `GrB_Matrix_free`, `GrB_Matrix_ncols`, `GrB_Matrix_nrows`, `GrB_get`, and of course `GrB_Matrix_setElement` itself. All other methods and operations cause the updates to be assembled. Future versions of SuiteSparse:GraphBLAS may extend this list.

See Section 17.2 for an example of how to use `GrB_Matrix_setElement`. If an error occurs, `GrB_error(&err,C)` returns details about the error.

#### 6.10.13 `GrB_Matrix_extractElement`: get an entry from a matrix

```
GrB_Info GrB_Matrix_extractElement      // x = A(i,j)
(
    <type> *x,                          // extracted scalar (non-opaque C scalar)
    const GrB_Matrix A,                 // matrix to extract a scalar from
    GrB_Index i,                        // row index
    GrB_Index j                         // column index
) ;
GrB_Info GrB_Matrix_extractElement      // x = A(i,j)
(
    GrB_Scalar x,                      // extracted GrB_Scalar
    const GrB_Matrix A,                 // matrix to extract a scalar from
    GrB_Index i,                        // row index
    GrB_Index j                         // column index
) ;
```

`GrB_Matrix_extractElement` extracts a single entry from a matrix `x=A(i,j)`. An error is returned (`GrB_INVALID_INDEX`) if the row index `i` is greater than

or equal to the number of rows of **C**, or if column index **j** is greater than or equal to the number of columns of **C**. If the entry is present, **x=A(i,j)** is performed and the scalar **x** is returned with this value. The method returns **GrB\_SUCCESS**. If no entry is present at **A(i,j)**, and **x** is a non-opaque **C** scalar, then **x** is not modified, and the return value of **GrB\_Matrix\_extractElement** is **GrB\_NO\_VALUE**. If **x** is a **GrB\_Scalar**, then **x** is returned as an empty scalar with no entry, and **GrB\_SUCCESS** is returned.

The function knows the type of the pointer **x**, so it can do typecasting as needed, from the type of **A** into the type of **x**. User-defined types cannot be typecasted, so if **A** has a user-defined type then **x** must be a **void \*** pointer that points to a memory space the same size as a single scalar of the type of **A**.

Currently, this method causes all pending updates from **GrB\_setElement**, **GrB\_assign**, or **GxB\_subassign** to be assembled, so its use can have performance implications. Calls to this function should not be arbitrarily inter-mixed with calls to these other two functions. Everything will work correctly and results will be predictable, it will just be slow.

#### 6.10.14 GxB\_Matrix\_isStoredElement: check if entry present in matrix

```
GrB_Info GxB_Matrix_isStoredElement
(
    const GrB_Matrix A,          // check for A(i,j)
    GrB_Index i,                // row index
    GrB_Index j                 // column index
) ;
```

**GxB\_Matrix\_isStoredElement** check if the single entry **A(i,j)** is present in the matrix **A**. It returns **GrB\_SUCCESS** if the entry is present, or **GrB\_NO\_VALUE** otherwise. The value of **A(i,j)** is not returned. It is otherwise identical to **GrB\_Matrix\_extractElement**.

### 6.10.15 GrB\_Matrix\_removeElement: remove an entry from a matrix

```
GrB_Info GrB_Matrix_removeElement
(
    GrB_Matrix C,           // matrix to remove an entry from
    GrB_Index i,           // row index
    GrB_Index j           // column index
) ;
```

`GrB_Matrix_removeElement` removes a single entry  $A(i,j)$  from a matrix. If no entry is present at  $A(i,j)$ , then the matrix is not modified. If an error occurs, `GrB_error(&err,A)` returns details about the error.

### 6.10.16 GrB\_Matrix\_extractTuples: get all entries from a matrix

```
GrB_Info GrB_Matrix_extractTuples          // [I,J,X] = find (A)
(
    GrB_Index *I,           // array for returning row indices of tuples
    GrB_Index *J,           // array for returning col indices of tuples
    <type> *X,              // array for returning values of tuples
    GrB_Index *nvals,       // I,J,X size on input; # tuples on output
    const GrB_Matrix A      // matrix to extract tuples from
) ;
```

`GrB_Matrix_extractTuples` extracts all the entries from the matrix  $A$ , returning them as a list of tuples, analogous to  $[I,J,X]=\text{find}(A)$  in MATLAB. Entries in the tuples  $[I,J,X]$  are unique. No pair of row and column indices  $(i,j)$  appears more than once.

The GraphBLAS API states the tuples can be returned in any order. If `GrB_wait` is called first, then SuiteSparse:GraphBLAS chooses to always return them in sorted order, depending on whether the matrix is stored by row or by column. Otherwise, the indices can be returned in any order.

The number of tuples in the matrix  $A$  is given by `GrB_Matrix_nvals(&anvals,A)`. If `anvals` is larger than the size of the arrays (`nvals` in the parameter list), an error `GrB_INSUFFICIENT_SIZE` is returned, and no tuples are extracted. If `nvals` is larger than `anvals`, then only the first `anvals` entries in the arrays  $I$ ,  $J$ , and  $X$  are modified, containing all the tuples of  $A$ , and the rest of  $I$ ,  $J$ , and  $X$  are left unchanged. On output, `nvals` contains the number of tuples extracted.

**SPEC:** As an extension to the specification, the arrays I, J, and/or X may be passed in as NULL pointers. `GrB_Matrix_extractTuples` does not return a component specified as NULL. This is not an error condition.

#### 6.10.17 `GxB_Matrix_extractTuples.Vector`: get all entries from a matrix

```
GrB_Info GrB_Matrix_extractTuples    // [I,J,X] = find (A)
(
    GrB_Vector I_vector,             // row indices
    GrB_Vector J_vector,             // col indices
    GrB_Vector X_vector,             // values
    const GrB_Matrix A,              // matrix to extract tuples from
    const GrB_Descriptor desc         // currently unused; for future expansion
) ;
```

`GxB_Matrix_extractTuples.Vector` is identical to `GrB_Matrix_extractTuples` except that its three outputs are `GrB_Vector` objects. The vectors `I_vector`, `J_vector`, and `X_vector` objects must exist on input. On output, any prior content is erased and their type, dimensions, and values are revised to contain dense vectors of length `nvals`.

#### 6.10.18 `GrB_Matrix_resize`: resize a matrix

```
GrB_Info GrB_Matrix_resize           // change the size of a matrix
(
    GrB_Matrix A,                    // matrix to modify
    const GrB_Index nrows_new,       // new number of rows in matrix
    const GrB_Index ncols_new       // new number of columns in matrix
) ;
```

`GrB_Matrix_resize` changes the size of a matrix. If the dimensions decrease, entries that fall outside the resized matrix are deleted. Unlike `GxB_Matrix_reshape*` (see Sections 6.10.19 and 6.10.20), entries remain in their same position after resizing the matrix.

### 6.10.19 GxB\_Matrix\_reshape: reshape a matrix

```
GrB_Info GxB_Matrix_reshape    // reshape a GrB_Matrix in place
(
    // input/output:
    GrB_Matrix C,                // input/output matrix, reshaped in place
    // input:
    bool by_col,                 // true if reshape by column, false if by row
    GrB_Index nrows_new,         // new number of rows of C
    GrB_Index ncols_new,         // new number of columns of C
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_reshape` changes the size of a matrix `C`, taking entries from the input matrix either column-wise or row-wise. If matrix `C` on input is `nrows`-by-`ncols`, and the requested dimensions of `C` on output are `nrows_new`-by-`ncols_new`, then the condition `nrows*ncols == nrows_new*ncols_new` must hold. The matrix `C` is modified in-place, as both an input and output for this method. To create a new matrix, use `GxB_Matrix_reshapeDup` instead (Section 6.10.20).

For example, if `C` is 3-by-4 on input, and is reshaped column-wise to have dimensions 2-by-6:

C on input	C on output (by_col true)
00 01 02 03	00 20 11 02 22 13
10 11 12 13	10 01 21 12 03 23
20 21 22 23	

If the same `C` on input is reshaped row-wise to dimensions 2-by-6:

C on input	C on output (by_col false)
00 01 02 03	00 01 02 03 10 11
10 11 12 13	12 13 20 21 22 23
20 21 22 23	

NOTE: because an intermediate linear index must be computed for each entry, `GxB_Matrix_reshape` cannot be used on matrices for which `nrows*ncols` exceeds  $2^{60}$ .

### 6.10.20 GxB\_Matrix\_reshapeDup: reshape a matrix

```
GrB_Info GxB_Matrix_reshapeDup // reshape a GrB_Matrix into another GrB_Matrix
(
    // output:
    GrB_Matrix *C,                // newly created output matrix, not in place
    // input:
    GrB_Matrix A,                // input matrix, not modified
    bool by_col,                 // true if reshape by column, false if by row
    GrB_Index nrows_new,         // number of rows of C
    GrB_Index ncols_new,         // number of columns of C
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_reshapeDup` is identical to `GxB_Matrix_reshape` (see Section 6.10.19), except that creates a new output matrix `C` that is reshaped from the input matrix `A`.

### 6.10.21 GxB\_Matrix\_concat: concatenate matrices

```
GrB_Info GxB_Matrix_concat      // concatenate a 2D array of matrices
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix *Tiles,     // 2D row-major array of size m-by-n
    const GrB_Index m,
    const GrB_Index n,
    const GrB_Descriptor desc    // unused, except threading control
) ;
```

`GxB_Matrix_concat` concatenates an array of matrices (`Tiles`) into a single `GrB_Matrix C`.

`Tiles` is an `m-by-n` dense array of matrices held in row-major format, where `Tiles [i*n+j]` is the  $(i, j)$ th tile, and where  $m > 0$  and  $n > 0$  must hold. Let  $A_{i,j}$  denote the  $(i, j)$ th tile. The matrix `C` is constructed by concatenating these tiles together, as:

$$C = \begin{bmatrix} A_{0,0} & A_{0,1} & A_{0,2} & \cdots & A_{0,n-1} \\ A_{1,0} & A_{1,1} & A_{1,2} & \cdots & A_{1,n-1} \\ \cdots & & & & \\ A_{m-1,0} & A_{m-1,1} & A_{m-1,2} & \cdots & A_{m-1,n-1} \end{bmatrix}$$

On input, the matrix `C` must already exist. Any existing entries in `C` are discarded. `C` must have dimensions `nrows` by `ncols` where `nrows` is the sum

of the number of rows in the matrices  $A_{i,0}$  for all  $i$ , and `ncols` is the sum of the number of columns in the matrices  $A_{0,j}$  for all  $j$ . All matrices in any given tile row  $i$  must have the same number of rows (that is, and all matrices in any given tile column  $j$  must have the same number of columns).

The type of `C` is unchanged, and all matrices  $A_{i,j}$  are typecasted into the type of `C`. Any settings made to `C` by `GrB_set` (format by row or by column, bitmap switch, hyper switch, and sparsity control) are unchanged.

### 6.10.22 GxB\_Matrix\_split: split a matrix

```
GrB_Info GxB_Matrix_split          // split a matrix into 2D array of matrices
(
    GrB_Matrix *Tiles,              // 2D row-major array of size m-by-n
    const GrB_Index m,
    const GrB_Index n,
    const GrB_Index *Tile_nrows,    // array of size m
    const GrB_Index *Tile_ncols,    // array of size n
    const GrB_Matrix A,             // input matrix to split
    const GrB_Descriptor desc        // unused, except threading control
);
```

`GxB_Matrix_split` does the opposite of `GxB_Matrix_concat`. It splits a single input matrix `A` into a 2D array of tiles. On input, the `Tiles` array must be a non-NULL pointer to a previously allocated array of size at least `m*n` where both `m` and `n` must be greater than zero. The `Tiles_nrows` array has size `m`, and `Tiles_ncols` has size `n`. The  $(i,j)$ th tile has dimension `Tiles_nrows[i]-by-Tiles_ncols[j]`. The sum of `Tiles_nrows [0:m-1]` must equal the number of rows of `A`, and the sum of `Tiles_ncols [0:n-1]` must equal the number of columns of `A`. The type of each tile is the same as the type of `A`; no typecasting is done.

### 6.10.23 GrB\_Matrix\_diag: construct a diagonal matrix

```
GrB_Info GrB_Matrix_diag          // construct a diagonal matrix from a vector
(
    GrB_Matrix *C,                  // output matrix
    const GrB_Vector v,             // input vector
    int64_t k
);
```

`GrB_Matrix_diag` constructs a matrix from a vector. Let  $n$  be the length of the `v` vector, from `GrB_Vector_size (&n, v)`. If  $k = 0$ , then `C` is an

$n$ -by- $n$  diagonal matrix with the entries from  $\mathbf{v}$  along the main diagonal of  $\mathbf{C}$ , with  $\mathbf{C}(i,i)=\mathbf{v}(i)$ . If  $k$  is nonzero,  $\mathbf{C}$  is square with dimension  $n + |k|$ . If  $k$  is positive, it denotes diagonals above the main diagonal, with  $\mathbf{C}(i,i+k)=\mathbf{v}(i)$ . If  $k$  is negative, it denotes diagonals below the main diagonal of  $\mathbf{C}$ , with  $\mathbf{C}(i-k,i)=\mathbf{v}(i)$ . This behavior is identical to the MATLAB statement  $\mathbf{C}=\text{diag}(\mathbf{v},k)$ , where  $\mathbf{v}$  is a vector.

The output matrix  $\mathbf{C}$  is a newly-constructed square matrix with the same type as the input vector  $\mathbf{v}$ . No typecasting is performed.

#### 6.10.24 GrB\_Matrix\_diag: build a diagonal matrix

```
GrB_Info GrB_Matrix_diag    // build a diagonal matrix from a vector
(
    GrB_Matrix C,            // output matrix
    const GrB_Vector v,      // input vector
    int64_t k,               // 
    const GrB_Descriptor desc // unused, except threading control
);
```

Identical to `GrB_Matrix_diag`, except for the extra parameter (a **descriptor** to provide control over the number of threads used), and this method is not a constructor.

The matrix  $\mathbf{C}$  must already exist on input, of the correct size. It must be square of dimension  $n + |k|$  where the vector  $\mathbf{v}$  has length  $n$ . Any existing entries in  $\mathbf{C}$  are discarded. The type of  $\mathbf{C}$  is preserved, so that if the type of  $\mathbf{C}$  and  $\mathbf{v}$  differ, the entries are typecasted into the type of  $\mathbf{C}$ . Any settings made to  $\mathbf{C}$  by `GrB_set` (format by row or by column, bitmap switch, hyper switch, and sparsity control) are unchanged.

#### 6.10.25 GrB\_Matrix\_memoryUsage: memory used by a matrix

```
GrB_Info GrB_Matrix_memoryUsage // return # of bytes used for a matrix
(
    size_t *size,            // # of bytes used by the matrix A
    const GrB_Matrix A       // matrix to query
);
```

Returns the memory space required for a matrix, in bytes. By default, any read-only components are not included in the total memory. This can be changed with via `GrB_set`; see Section [10.2](#).

### 6.10.26 GxB\_Matrix\_type: type of a matrix

```
GrB_Info GxB_Matrix_type    // get the type of a matrix
(
    GrB_Type *type,          // returns the type of the matrix
    const GrB_Matrix A       // matrix to query
) ;
```

Returns the type of a matrix. The `type` parameter is not allocated. Calling `GxB_Matrix_type` is identical to making a shallow pointer copy of the type used to create a matrix. In particular, suppose a matrix is created, and a copy of its type is saved at the same time:

```
GrB_Matrix_new (&A, atype, m, n) ;
GrB_Type save_type = atype ;
```

Sometime later, while the matrix `A` and its type `atype` have not been freed, the following two code fragments are identical:

```
// using GxB_Matrix_type:
GrB_Type atype2 ;
GxB_Matrix_type (&atype2, A) ;
assert (atype2 == save_type) ;

// without GxB_Matrix_type:
GrB_Type atype2 = save_type ;
```

As a result, freeing `atype2` would be the same as freeing the original `atype`.

### 6.10.27 GrB\_Matrix\_free: free a matrix

```
GrB_Info GrB_free           // free a matrix
(
    GrB_Matrix *A            // handle of matrix to free
) ;
```

`GrB_Matrix_free` frees a matrix. Either usage:

```
GrB_Matrix_free (&A) ;
GrB_free (&A) ;
```

frees the matrix `A` and sets `A` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `A == NULL` on input. Any pending updates to the matrix are abandoned.

## 6.11 Serialize/deserialize methods

*Serialization* takes an opaque GraphBLAS object (a vector or matrix) and encodes it in a single non-opaque array of bytes, the *blob*. The blob can only be deserialized by the same library that created it (SuiteSparse:GraphBLAS in this case). The array of bytes can be written to a file, sent to another process over an MPI channel, or operated on in any other way that moves the bytes around. The contents of the array cannot be interpreted except by deserialization back into a vector or matrix, by the same library (and sometimes the same version) that created the blob.

All versions of SuiteSparse:GraphBLAS that implement serialization/deserialization use essentially the same format for the blob, so the library versions are compatible with each other. Version v9.0.0 adds the `GrB_NAME` and `GrB_EL_TYPE_STRING` to the blob in an upward compatible manner, so that older versions of SuiteSparse:GraphBLAS can read the blobs created by v9.0.0; they simply ignore those components.

SuiteSparse:GraphBLAS v10 adds 32/64-bit integers, and can read the blobs created by any prior version of GraphBLAS (they are deserialized with all 64-bit integers however). If an older version of SuiteSparse:GraphBLAS (v9 or earlier) attempts to deserialize a blob containing a matrix with 32-bit integers, it will safely report that the blob is invalid and refuse to deserialize it. If SuiteSparse:GraphBLAS v10 creates a serialized blob with all-64-bit integers, then it can be read correctly by SuiteSparse:GraphBLAS v9, and likely also by earlier versions of the library.

There are two forms of serialization: `GrB*serialize` and `GxB*serialize`. For the `GrB` form, the blob must first be allocated by the user application, and it must be large enough to hold the serialized matrix or vector. By contrast `GxB*serialize` allocates the blob itself.

By default, ZSTD (level 1) compression is used for serialization, but other options can be selected via the descriptor: `GrB_set (desc, method, GxB_COMPRESSION)`, where `method` is an integer selected from the following options:

method	description
<code>GxB_COMPRESSION_NONE</code>	no compression
<code>GxB_COMPRESSION_DEFAULT</code>	ZSTD, with default level 1
<code>GxB_COMPRESSION_LZ4</code>	LZ4
<code>GxB_COMPRESSION_LZ4HC</code>	LZ4HC, with default level 9
<code>GxB_COMPRESSION_ZSTD</code>	ZSTD, with default level 1

The LZ4HC method can be modified by adding a level of zero to 9, with 9 being the default. Higher levels lead to a more compact blob, at the cost of extra computational time. This level is simply added to the method, so to compress a vector with LZ4HC with level 6, use:

```
GrB_set (desc, GxB_COMPRESSION_LZ4HC + 6, GxB_COMPRESSION) ;
```

The ZSTD method can be specified as level 1 to 19, with 1 being the default. To compress with ZSTD at level 6, use:

```
GrB_set (desc, GxB_COMPRESSION_ZSTD + 6, GxB_COMPRESSION) ;
```

Deserialization of untrusted data is a common security problem; see <https://cwe.mitre.org/data/definitions/502.html>. The deserialization methods in SuiteSparse:GraphBLAS do a few basic checks so that no out-of-bounds access occurs during deserialization, but the output matrix or vector itself may still be corrupted. If the data is untrusted, use `GxB*_fprint` with the print level set to `GxB_SILENT` to check the matrix or vector after deserializing it:

```
info = GxB_Vector_fprint (w, "w deserialized", GxB_SILENT, NULL) ;
if (info != GrB_SUCCESS) GrB_free (&w) ;
info = GxB_Matrix_fprint (A, "A deserialized", GxB_SILENT, NULL) ;
if (info != GrB_SUCCESS) GrB_free (&A) ;
```

The following methods are described in this Section:

GraphBLAS function	purpose	Section
<code>GxB_Vector_serialize</code>	serialize a vector	<a href="#">6.11.1</a>
<code>GxB_Vector_deserialize</code>	deserialize a vector	<a href="#">6.11.2</a>
<code>GrB_Matrix_serializeSize</code>	return size of serialized matrix	<a href="#">6.11.3</a>
<code>GrB_Matrix_serialize</code>	serialize a matrix	<a href="#">6.11.4</a>
<code>GxB_Matrix_serialize</code>	serialize a matrix	<a href="#">6.11.5</a>
<code>GrB_Matrix_deserialize</code>	deserialize a matrix	<a href="#">6.11.6</a>
<code>GxB_Matrix_deserialize</code>	deserialize a matrix	<a href="#">6.11.7</a>
<code>GrB_get</code>	get blob properties	<a href="#">10.16</a>

### 6.11.1 GxB\_Vector\_serialize: serialize a vector

```
GrB_Info GxB_Vector_serialize      // serialize a GrB_Vector to a blob
(
    // output:
    void **blob_handle,            // the blob, allocated on output
    GrB_Index *blob_size_handle,   // size of the blob on output
    // input:
    GrB_Vector u,                  // vector to serialize
    const GrB_Descriptor desc      // descriptor to select compression method
) ;
```

`GxB_Vector_serialize` serializes a vector into a single array of bytes (the blob), which is `malloc`'ed and filled with the serialized vector. By default, ZSTD (level 1) compression is used, but other options can be selected via the descriptor. Serializing a vector is identical to serializing a matrix; see Section 6.11.5 for more information.

### 6.11.2 GxB\_Vector\_deserialize: deserialize a vector

```
GrB_Info GxB_Vector_deserialize    // deserialize blob into a GrB_Vector
(
    // output:
    GrB_Vector *w,                // output vector created from the blob
    // input:
    GrB_Type type,                // type of the vector w. See GxB_Matrix_deserialize.
    const void *blob,             // the blob
    GrB_Index blob_size,          // size of the blob
    const GrB_Descriptor desc
) ;
```

This method creates a vector `w` by deserializing the contents of the blob, constructed by `GxB_Vector_serialize`. Deserializing a vector is identical to deserializing a matrix; see Section 6.11.7 for more information.

The blob is allocated with the `malloc` function passed to `GxB_init`, or the C11 `malloc` if `GrB_init` was used to initialize GraphBLAS. The blob must be freed by the matching `free` method, either the `free` function passed to `GxB_init` or the C11 `free` if `GrB_init` was used.

### 6.11.3 GrB\_Matrix\_serializeSize: return size of serialized matrix

```
GrB_Info GrB_Matrix_serializeSize    // estimate the size of a blob
(
    // output:
    GrB_Index *blob_size_handle,      // upper bound on the required size of the
                                      // blob on output.

    // input:
    GrB_Matrix A                      // matrix to serialize
) ;
```

`GrB_Matrix_serializeSize` returns an upper bound on the size of the blob needed to serialize a `GrB_Matrix` with `GrB_Matrix_serialize`. After the matrix is serialized, the actual size used is returned, and the blob may be `realloc`'d to that size if desired. This method is not required for `GxB_Matrix_serialize`.

### 6.11.4 GrB\_Matrix\_serialize: serialize a matrix

```
GrB_Info GrB_Matrix_serialize        // serialize a GrB_Matrix to a blob
(
    // output:
    void *blob,                      // the blob, already allocated in input
    // input/output:
    GrB_Index *blob_size_handle,      // size of the blob on input. On output,
                                      // the # of bytes used in the blob.

    // input:
    GrB_Matrix A                      // matrix to serialize
) ;
```

`GrB_Matrix_serialize` serializes a matrix into a single array of bytes (the blob), which must be already allocated by the user application. On input, `&blob_size` is the size of the allocated blob in bytes. On output, it is reduced to the number of bytes actually used to serialize the matrix. After calling `GrB_Matrix_serialize`, the blob may be `realloc`'d to this revised size if desired (this is optional). ZSTD (level 1) compression is used to construct a compact blob.

### 6.11.5 GxB\_Matrix\_serialize: serialize a matrix

```
GrB_Info GxB_Matrix_serialize      // serialize a GrB_Matrix to a blob
(
    // output:
    void **blob_handle,             // the blob, allocated on output
    GrB_Index *blob_size_handle,    // size of the blob on output
    // input:
    GrB_Matrix A,                  // matrix to serialize
    const GrB_Descriptor desc       // descriptor to select compression method
) ;
```

`GxB_Matrix_serialize` is identical to `GrB_Matrix_serialize`, except that it does not require a pre-allocated blob. Instead, it allocates the blob internally, and fills it with the serialized matrix. By default, ZSTD (level 1) compression is used, but other options can be selected via the descriptor.

The blob is allocated with the `malloc` function passed to `GxB_init`, or the C11 `malloc` if `GrB_init` was used to initialize GraphBLAS. The blob must be freed by the matching `free` method, either the `free` function passed to `GxB_init` or the C11 `free` if `GrB_init` was used.

### 6.11.6 GrB\_Matrix\_deserialize: deserialize a matrix

```
GrB_Info GrB_Matrix_deserialize    // deserialize blob into a GrB_Matrix
(
    // output:
    GrB_Matrix *C,                 // output matrix created from the blob
    // input:
    GrB_Type type,                 // type of the matrix C. Required if the blob holds a
                                   // matrix of user-defined type. May be NULL if blob
                                   // holds a built-in type; otherwise must match the
                                   // type of C.
    const void *blob,              // the blob
    GrB_Index blob_size            // size of the blob
) ;
```

This method creates a matrix `A` by deserializing the contents of the blob, constructed by either `GrB_Matrix_serialize` or `GxB_Matrix_serialize`.

The `type` may be `NULL` if the blob holds a serialized matrix with a built-in type. In this case, the type is determined automatically. For user-defined types, the `type` must match the type of the matrix in the blob. The `GrB_get` method can be used to query the blob for the name of this type.

### 6.11.7 GxB\_Matrix\_deserialize: deserialize a matrix

```
GrB_Info GxB_Matrix_deserialize    // deserialize blob into a GrB_Matrix
(
    // output:
    GrB_Matrix *C,                // output matrix created from the blob
    // input:
    GrB_Type type,                // type of the matrix C. Required if the blob holds a
                                // matrix of user-defined type. May be NULL if blob
                                // holds a built-in type; otherwise must match the
                                // type of C.
    const void *blob,             // the blob
    GrB_Index blob_size,          // size of the blob
    const GrB_Descriptor desc
) ;
```

Identical to GrB\_Matrix\_deserialize.

## 6.12 The GxB\_Container object and its methods

A new set of load/unload methods are introduced in GraphBLAS v10 to move data between a `GrB_Matrix` or `GrB_Vector` and a new `GxB_Container` object. This object is non-opaque but contains opaque objects. Its primary components are five dense `GrB_Vectors` that hold the contents of the matrix/vector. The data in these dense vectors can then be loaded/unloaded via `GxB_Vector_load` and `GxB_Vector_unload`.

Moving data from a `GrB_Matrix` into user-visible C arrays is a two-step process. The data is first moved into a `GxB_Container` using `GxB_unload_Matrix_into_Container`, and then from the Container into C arrays with `GxB_Vector_unload`. Moving data in the opposite direction is also a two-step process: first load the C array into a `GrB_Vector` component of a `GxB_Container` with `GxB_Vector_load`, and then from the `GxB_Container` into a `GrB_Matrix` using the `GxB_load_Matrix_from_Container` method.

The following methods are available. The first two do not use the Container object, but instead move data to/from a dense `GrB_Vector`:

- `GxB_Vector_load`: this method moves data in  $O(1)$  time from a user-visible C array into a `GrB_Vector`. The vector length and type are revised to match the new data from the C array. Ownership is normally transferred to the `GrB_Vector`, but this can be revised with a `handling` parameter. The C array is passed in as a `void *` pointer, and its type is indicated by a `GrB_Type` parameter. See Section 6.12.1 for details.
- `GxB_Vector_unload`: this method moves data in  $O(1)$  time from a `GrB_Vector` into a user-visible C array. The length of the `GrB_Vector` is reduced to zero, to denote that it no longer holds any content. The vector must be dense; it must have the same number of entries as its size (that is `GrB_Vector_nvals` and `GrB_Vector_size` must return the same value). The C array is returned as a `void *` pointer, and its type is indicated by a `GrB_Type` parameter. See Section 6.12.2 for details.

The next six methods rely on the `GxB_Container` object:

- `GxB_Container_new`: creates a container (see Section 6.12.3).
- `GxB_Container_free`: frees a container (see Section 6.12.4).

- `GxB_load_Matrix_from_Container`: moves all of the data from a `GxB_Container` into a `GrB_Matrix` in  $O(1)$  time (see Section 6.12.5).
- `GxB_load_Vector_from_Container`: moves all of the data from a `GxB_Container` into a `GrB_Vector` in  $O(1)$  time (see Section 6.12.6).
- `GxB_unload_Matrix_into_Container`: moves all of the data from a `GrB_Matrix` into a `GxB_Container` in  $O(1)$  time (see Section 6.12.7).
- `GxB_unload_Vector_into_Container`: moves all of the data from a `GrB_Vector` into a `GxB_Container` in  $O(1)$  time (see Section 6.12.8).

### 6.12.1 `GxB_Vector_load`: load data into a vector

```
GrB_Info GxB_Vector_load
(
    // input/output:
    GrB_Vector V,           // vector to load from the C array X
    void **X,              // numerical array to load into V
    // input:
    GrB_Type type,         // type of X
    uint64_t n,            // # of entries in X
    uint64_t X_size,       // size of X in bytes (at least n*(sizeof the type))
    int handling,          // GrB_DEFAULT (0): transfer ownership to GraphBLAS
                          // GxB_IS_READONLY: X treated as read-only;
                          // ownership kept by the user application
    const GrB_Descriptor desc // currently unused; for future expansion
) ;
```

`GxB_Vector_load` loads data from a C array into a `GrB_Vector` in  $O(1)$  time.

On input, the `GrB_Vector` `V` must already exist, but its content (type, size, and entries) are ignored. On output, any prior content of `V` is freed, and its data is replaced with the C array `X` of length `n` entries, whose type is given by the `type` parameter. The size of `V` becomes `n`, and its type is changed to match the `type` parameter.

After this method returns, `GrB_Vector_size` and `GrB_Vector_nvals` will both return `n`. That is, the vector `V` is a dense vector. It is held in the `GxB_FULL` data format, in `GrB_COLMAJOR` orientation.

The size in bytes of `X` is also provided on input as `X_size`; this must be at least `n` times the size of the given `type`, but it can be larger. This size

is maintained and returned to the user application by `GxB_Vector_unload`. The error code `GrB_INVALID_VALUE` is returned if `X_size` is too small.

The `handling` parameter provides control over the ownership of the array `X`. By default, ownership of `X` is handed over to the `GrB_Vector V`. In this case, the vector `V` acts as a normal GraphBLAS vector. It can be modified or freed as usual. Freeing `V` with `GrB_Vector_free` will also free `X`. The array `X` is returned as `NULL` to denote this change of ownership.

If the `handling` parameter is `GxB_IS_READONLY`, then `X` is still owned by the user application. It remains non-`NULL` when this method returns. The resulting vector `V` can be used as an input to any GraphBLAS method, but it cannot be modified (except that it can be freed). If a call is made that attempts to modify a matrix with read-only components, an error is returned (`GxB_OUTPUT_IS_READONLY`). Freeing the vector `V` does not modify `X`, however. It simply frees the rest of the object `V`.

Note that this method does not rely on the `GxB_Container` object. Instead, it loads a C array `X` directly into a dense `GrB_Vector V`.

### 6.12.2 `GxB_Vector_unload`: unload data from a vector

```
GrB_Info GxB_Vector_unload
(
    // input/output:
    GrB_Vector V,           // vector to unload
    void **X,              // numerical array to unload from V
    // output:
    GrB_Type *type,         // type of X
    uint64_t *n,           // # of entries in X
    uint64_t *X_size,       // size of X in bytes (at least n*(sizeof the type))
    int *handling,          // see GxB_Vector_load
    const GrB_Descriptor desc // currently unused; for future expansion
) ;
```

`GxB_Vector_unload` unloads data from `GrB_Vector` into a C array in  $O(1)$  time (unless the vector has pending work that must be finished first).

On input, the vector `V` must have all possible entries present (that is, `GrB_Vector_nvals` and `GrB_Vector_size` must return the same value). The vector can be in any internal data format; it does not have to be in the `GxB_FULL` format on input, but it must be in `GrB_COLMAJOR` orientation. If any entries are missing, the unload is not performed and `GrB_INVALID_OBJECT` is returned.

On output, the size of *V* is reduced to zero, and it holds no entries but its type is unchanged. The array *X* is returned to the caller with the entries from the vector. The type of *X* is given by the **type** parameter. The number of entries in *V* is returned as *n*. The size of *X* in bytes is returned as *X\_size*.

The **handling** parameter informs the user application of the ownership of the array *X*. If it was created by GraphBLAS, or passed into GraphBLAS via *GxB\_Vector\_load* with **handling** set to *GrB\_DEFAULT*, then this is returned to the user as **handling** set to *GrB\_DEFAULT*. This denotes that ownership of the array *X* has been transferred from GraphBLAS to the user application. The user application is now responsible for freeing the array *X*.

If the **handling** parameter is returned as *GxB\_IS\_READONLY*, then this array *X* was originally passed to GraphBLAS via *GxB\_Vector\_load* with a **handling** parameter of *GxB\_IS\_READONLY*. The ownership of the array *X* is not changed; it remains owned by the user application. The user application is still responsible for freeing the array *X*, but caution must be observed so that it is not freed twice.

Note that this method does not rely on the *GxB\_Container* object. Instead, it unloads a dense *GrB\_Vector* *V* directly into a C array *X*.

### 6.12.3 *GxB\_Container\_new*: create a container

```
GrB_Info GxB_Container_new (GxB_Container *Container) ;
```

*GxB\_Container\_new* creates a new container. It has the following definition (extra space for future expansion excluded for clarity):

```
struct GxB_Container_struct
{
    uint64_t nrows, ncols ;
    int64_t nrows_nonempty, ncols_nonempty ;
    uint64_t nvals ;
    int32_t format ;          // GxB_HYPERSPARSE, GxB_SPARSE, GxB_BITMAP, or GxB_FULL
    int32_t orientation ;    // GrB_ROWMAJOR or GrB_COLMAJOR
    GrB_Vector p, h, b, i, x ; // dense vector components
    GrB_Matrix Y ;
    bool iso, jumbled ;
} ;
typedef struct GxB_Container_struct *GxB_Container ;
```

The *Container* holds all of the data from a single GraphBLAS matrix or vector, with any data type and any data format. It contains extra space for

future data formats (not shown above). Each scalar component is described below:

- **nrows**: the number of rows of a matrix, or the size of a vector.
- **ncols**: the number of columns of a matrix, or 1 for a vector.
- **nrows\_nonempty**: if known, this value must give the exact number of non-empty rows of a matrix or vector (that is, the number of rows have at least one entry). If not known, this value must be set to -1.
- **ncols\_nonempty**: if known, this value must give the exact number of non-empty columns of a matrix or vector (that is, the number of columns have at least one entry). If not known, this value must be set to -1.
- **nvals**: the number of entries in the matrix or vector.
- **format**: this defines the data format of a matrix or vector. Currently, GraphBLAS supports four formats, described in Section 6.13, each with two orientations. A **GrB\_Vector** cannot be held in **GxB\_HYPERSPARSE** format.
- **orientation**: whether the matrix is held by row or by column. This is always **GrB\_COLMAJOR** for a container holding data for a **GrB\_Vector**, and for data holding an  $n$ -by-1 **GrB\_Matrix** with a single column.
- **iso**: if true, all of the entries in the matrix have the same value, and only a single value is stored in the **x** component of the Container.
- **jumbled**: if true, the indices in any given row (if in row-major orientation) or column (if column-major) may appear out of order. Otherwise, they must appear in ascending order. A jumbled matrix or vector must not have any read-only components.

The Container holds five dense **GrB\_Vector** objects that hold the primary data for the matrix or vector, and a single **GrB\_Matrix Y** that holds an optional optimization structure called the hyper-hash. These components are fully described in Section 6.13.

#### 6.12.4 GxB\_Container\_free: free a container

```
GrB_Info GrB_free (GxB_Container *Container) ;
```

`GxB_Container_free` frees a container. It also frees all its opaque components. Any read-only array inside these opaque objects is not freed.

#### 6.12.5 GxB\_load\_Matrix\_from\_Container: load a matrix from a container

```
GrB_Info GxB_load_Matrix_from_Container      // GrB_Matrix <- GxB_Container
(
    GrB_Matrix A,                          // matrix to load from the Container.  On input,
                                           // A is a matrix of any size or type; on output
                                           // any prior size, type, or contents is freed
                                           // and overwritten with the Container.
    GxB_Container Container,               // Container with contents to load into A
    const GrB_Descriptor desc              // currently unused
) ;
```

`GxB_load_Matrix_from_Container` moves all of the data from a `GxB_Container` into a `GrB_Matrix` in  $O(1)$  time.

The container vectors `p`, `h`, and `i` may be any signed or unsigned integer type of size 32 or 64 bits. Any other types will result in an error.

#### 6.12.6 GxB\_load\_Vector\_from\_Container: load a vector from a container

```
GrB_Info GxB_load_Vector_from_Container      // GrB_Vector <- GxB_Container
(
    GrB_Vector V,                          // GrB_Vector to load from the Container
    GxB_Container Container,               // Container with contents to load into V
    const GrB_Descriptor desc              // currently unused
) ;
```

`GxB_load_Vector_from_Container` moves all of the data from a `GxB_Container` into a `GrB_Vector` in  $O(1)$  time.

The container format may not be `GxB_HYPERSPARSE`. The container vectors `p` and `i` may be any signed or unsigned integer type of size 32 or 64 bits. Any other types will result in an error.

### 6.12.7 GxB\_unload\_Matrix\_into\_Container: unload a matrix into a container

```
GrB_Info GxB_unload_Matrix_into_Container    // GrB_Matrix -> GxB_Container
(
    GrB_Matrix A,                          // matrix to unload into the Container
    GxB_Container Container,                // Container to hold the contents of A
    const GrB_Descriptor desc               // currently unused
) ;
```

GxB\_unload\_Matrix\_into\_Container: moves all of the data from a GrB\_Matrix into a GxB\_Container in  $O(1)$  time.

The container vector `p` is unloaded as GrB\_UINT32 or GrB\_UINT64, while `h`, and `i` are unloaded as GrB\_INT32 or GrB\_INT64.

### 6.12.8 GxB\_unload\_Vector\_into\_Container: unload a vector into a container

```
GrB_Info GxB_unload_Vector_into_Container    // GrB_Vector -> GxB_Container
(
    GrB_Vector V,                          // vector to unload into the Container
    GxB_Container Container,                // Container to hold the contents of V
    const GrB_Descriptor desc               // currently unused
) ;
```

GxB\_unload\_Vector\_into\_Container: moves all of the data from a GrB\_Vector into a GxB\_Container in  $O(1)$  time.

The container vector `p` is unloaded as GrB\_UINT32 or GrB\_UINT64, while `i` is unloaded as GrB\_INT32 or GrB\_INT64.

### 6.12.9 Container example: unloading/loading an entire matrix into C arrays

The following example unloads a GrB\_Matrix `A` of size `nrows-by-ncols`, with `nvals` entries, of type `xtype`. The example takes will take  $O(1)$  time, and the only `mallocs` are in `GxB_Container_new` (which can be reused for an arbitrary number of load/unload cycles), and the only `frees` are in `GxB_Container_free`.

Note that getting C arrays from a GrB\_Matrix is a 2-step process: First unload the matrix `A` into a Container, giving GrB\_Vector objects `Container->p`, `Container->i`, `Container->x`, etc, and then unload those dense vectors into

C arrays. This may seem tedious but it allows everything to be done in  $O(1)$  time and space (often no new malloc'd space), and it allows support for arbitrary integers for the *p*, *h*, and *i* components of a matrix. It also makes for a simple API overall.

```
GxB_Container_new (&Container) ;    // requires several  $O(1)$ -sized mallocs

// no malloc/free will occur below, until GxB_Container_free.

for (as many times as you like)
{

    GxB_unload_Matrix_into_Container (A, Container, desc) ;
    // A is now 0-by-0 with nvals(A)=0.  Its type is unchanged.

    // All of the following is optional; if any item in the Container is not
    // needed by the user, it can be left as-is, and then it will be put
    // back into A at the end.  (This is done for the Container->Y).

    // to extract numerical values from the Container:
    void *x = NULL ;
    uint64_t nvals = 0, nheld = 0 ;
    GrB_Type xtype = NULL ;
    int x_handling, p_handling, h_handling, i_handling, b_handling ;
    uint64_t x_size, p_size, h_size, i_size, b_size ;
    GxB_Vector_unload (Container->x, &x, &xtype, &nheld, &x_size, &x_handling,
        desc) ;

    // The C array x now has size nheld and contains the values of the original
    // GrB_Matrix A, with type xtype being the original type of the matrix A.
    // The Container->x GrB_Vector still exists but it now has length 0.
    // If the matrix A was iso-valued, nheld == 1.

    // to extract the sparsity pattern from the Container:
    GrB_Type ptype = NULL, htype = NULL, itype = NULL, btype = NULL ;
    void *p = NULL, *h = NULL, *i = NULL, *b = NULL ;
    uint64_t plen = 0, plen1 = 0, nheld = 0 ;

    switch (Container->format)
    {
        case GxB_HYPERSPARSE :
            // The Container->Y matrix can be unloaded here as well,
            // if desired.  Its use is optional.
            GxB_Vector_unload (Container->h, &h, &htype, &plen, &h_size,
                &h_handling, desc) ;
```

```

    case GxB_SPARSE :
        GxB_Vector_unload (Container->p, &p, &ptype, &plen1, &p_size,
            &p_handling, desc) ;
        GxB_Vector_unload (Container->i, &i, &itype, &nvals, &i_size,
            &i_handling, desc) ;
        break ;
    case GxB_BITMAP :
        GxB_Vector_unload (Container->b, &b, &btype, &nheld, &b_size,
            &b_handling, desc) ;
        break ;
}

// Now the C arrays (p, h, i, b, and x) are all populated and owned by the
// user application. They can be modified here, if desired. Their C type
// is (void *), and their actual types correspond to ptype, htype, itype,
// btype, and xtype).

// to load them back into A, first load them into the Container->[phbix]
// vectors:
switch (Container->format)
{
    case GxB_HYPERSPARSE :
        // The Container->Y matrix can be loaded here as well,
        // if desired. Its use is optional.
        GxB_Vector_load (Container->h, &h, htype, plen, h_size,
            h_handling, desc) ;
    case GxB_SPARSE :
        GxB_Vector_load (Container->p, &p, ptype, plen1, p_size,
            p_handling, desc) ;
        GxB_Vector_load (Container->i, &i, itype, nvals, i_size,
            i_handling, desc) ;
        break ;
    case GxB_BITMAP :
        GxB_Vector_load (Container->b, &b, btype, nheld, b_size,
            b_handling, desc) ;
        break ;
}
GxB_Vector_load (Container->x, &x, xtype, nheld, x_size,
    x_handling, desc) ;

// Now the C arrays p, h, i, b, and x are all NULL. They are in the
// Container->p,h,b,i,x GrB_Vectors. Load A from the non-opaque Container:

GxB_load_Matrix_from_Container (A, Container, desc) ;
// A is now back to its original state. The Container and its p,h,b,i,x

```

```

    // GrB_Vectors exist but its vectors all have length 0.
}

GxB_Container_free (&Container) ;    // does several O(1)-sized free's

```

#### 6.12.10 Container example: unloading/loading, but not using C arrays

Using the container is very simple if the resulting Container `GrB_Vector` components are used directly by GraphBLAS, with no need for C arrays. For example, in a push/relabel maxflow algorithm, there is a need to extract the tuples from a `GrB_Vector Delta`, followed by a call to `GrB_Matrix_build` to create a matrix from that data. In GraphBLAS v9 and earlier, extracting the tuples requires a copy. In v10, it can be done using the container, without requiring a copy of the contents of `Delta`.

```

GxB_Container_new (&Container) ;
for (...)
{
    GrB_Vector Delta, J_Vector ;    // computed by GraphBLAS (not shown)
    GrB_Matrix DeltaMatrix ;
    ...
    GxB_unload_Vector_into_Container (Delta, Container, desc) ;
    GxB_Matrix_build_Vector (DeltaMatrix, Container->i, J_vector,
        Container->x, GrB_PLUS_FP32, NULL) ;
    GxB_load_Vector_from_Container (Delta, Container, desc) ;
}
GxB_Container_free (&Container) ;

```

The contents of the `Delta` vector can be used unloaded in to the container for use by `GxB_Matrix_build_Vector`, in  $O(1)$  time, and then loaded back afterwards, also in  $O(1)$  time. The construction of the `DeltaMatrix` takes the same time as `GrB_Matrix_build`, but the extra copy that would be required for `GrB_Vector_extractTuples` is entirely avoided.

## 6.13 SuiteSparse:GraphBLAS data formats

SuiteSparse:GraphBLAS uses four distinct data formats: sparse, hypersparse, bitmap, and full, each in row-major or column-major orientations, for eight different variants (each of which are listed below). Each of these eight total variants can be iso-valued, where if `Container->iso` is true the numerical values are all the same, and `Container->x` holds a single entry with this value. Each of the sparse and hypersparse formats can appear in *jumbled* form, where the indices within any given row (if the orientation is row-major) or column may be out of order. If `Container->jumbled` is false, then the indices appear in ascending order.

The `p`, `h`, and `i` vectors in the Container have an integer type, either `GrB_UINT32` or `GrB_UINT64`. These appear below as just `integer`, but the actual corresponding C type (`uint32_t` or `uint64_t`) must be used for each component.

### 6.13.1 Sparse, held by row

A sparse matrix in CSR format, held by row, has a `Container->format` value of `GxB_SPARSE` and a `Container->orientation` of `GrB_ROWMAJOR`. It requires three arrays:

- `integer Ap [nrows+1]` ; The `Ap` array is the row “pointer” array. It does not actual contain pointers, but integer offsets. More precisely, it is an integer array that defines where the column indices and values appear in `Aj` and `Ax`, for each row. The number of entries in row `i` is given by the expression `Ap [i+1] - Ap [i]`.
- `integer Aj [nvals]` ; The `Aj` array defines the column indices of entries in each row.
- `type Ax [nvals]` ; The `Ax` array defines the values of entries in each row.

The content of the three arrays `Ap`, `Aj`, and `Ax` is very specific. This content is not checked, since this function takes only  $O(1)$  time. Results are undefined if the following specification is not followed exactly.

The column indices of entries in the `i`th row of the matrix are held in `Aj [Ap [i] ... Ap[i+1]]`, and the corresponding values are held in the

same positions in **Ax**. Column indices must be in the range 0 to **ncols**-1. If **jumbled** is **false**, column indices must appear in ascending order within each row. If **jumbled** is **true**, column indices may appear in any order within each row. No duplicate column indices may appear in any row. **Ap** [0] must equal zero, and **Ap** [**nrows**] must equal **nvals**. The **Ap** array must be of size **nrows**+1 (or larger), and the **Aj** and **Ax** arrays must have size at least **nvals**.

An example of the CSR format is shown below. Consider the following matrix with 10 nonzero entries, and suppose the zeros are not stored.

$$A = \begin{bmatrix} 4.5 & 0 & 3.2 & 0 \\ 3.1 & 2.9 & 0 & 0.9 \\ 0 & 1.7 & 3.0 & 0 \\ 3.5 & 0.4 & 0 & 1.0 \end{bmatrix} \quad (1)$$

The **Ap** array has length 5, since the matrix is 4-by-4. The first entry must always zero, and **Ap** [5] = 10 is the number of entries. The content of the arrays is shown below:

```
integer Ap [ ] = { 0,      2,      5,      7,      10 } ;
integer Aj [ ] = { 0,  2,  0,  1,  3,  1,  2,  0,  1,  3 } ;
double Ax [ ] = { 4.5, 3.2, 3.1, 2.9, 0.9, 1.7, 3.0, 3.5, 0.4, 1.0 } ;
```

Spaces have been added to the **Ap** array, just for illustration. Row zero is in **Aj** [0..1] (column indices) and **Ax** [0..1] (values), starting at **Ap** [0] = 0 and ending at **Ap** [0+1]-1 = 1. The list of column indices of row one is at **Aj** [2..4] and row two is in **Aj** [5..6]. The last row (three) appears **Aj** [7..9], because **Ap** [3] = 7 and **Ap** [4]-1 = 10-1 = 9. The corresponding numerical values appear in the same positions in **Ax**.

To iterate over the rows and entries of this matrix, the following code can be used (assuming it has type **GrB\_FP64**):

```
integer nvals = Ap [nrows] ;
for (integer i = 0 ; i < nrows ; i++)
{
    // get A(i,:)
    for (integer p = Ap [i] ; p < Ap [i+1] ; p++)
    {
        // get A(i,j)
        integer j = Aj [p] ;           // column index
        double aij = Ax [iso ? 0 : p] ; // numerical value
    }
}
```

In the container, the three arrays **Ap**, **Aj** and **Ax** are held in three **GrB\_Vector** objects: **Container->p**, **Container->i**, and **Container->x**, respectively.

### 6.13.2 Sparse, held by column

This format is the transpose of sparse-by-row. A sparse matrix in CSC format, held by column, has a **Container->format** value of **GxB\_SPARSE** and a **Container->orientation** of **GrB\_COLMAJOR**. It requires three arrays: **Ap**, **Ai**, and **Ax**.

The column “pointer” array **Ap** has size **ncols+1**. The row indices of the columns are in **Ai**, and if **jumbled** is false, they must appear in ascending order in each column. The corresponding numerical values are held in **Ax**. The row indices of column **j** are held in **Ai [Ap [j]...Ap [j+1]-1]**, and the corresponding numerical values are in the same locations in **Ax**.

The same matrix from Equation 1 in the last section (repeated here):

$$A = \begin{bmatrix} 4.5 & 0 & 3.2 & 0 \\ 3.1 & 2.9 & 0 & 0.9 \\ 0 & 1.7 & 3.0 & 0 \\ 3.5 & 0.4 & 0 & 1.0 \end{bmatrix} \quad (2)$$

is held in CSC form as follows:

```
integer Ap [ ] = { 0,           3,           6,           8,          10 } ;
integer Ai [ ] = { 0,   1,   3,   1,   2,   3,   0,   2,   1,   3   } ;
double Ax [ ] = { 4.5, 3.1, 3.5, 2.9, 1.7, 0.4, 3.2, 3.0, 0.9, 1.0 } ;
```

That is, the row indices of column 1 (the second column) are in **Ai [3..5]**, and the values in the same place in **Ax**, since **Ap [1] = 3** and **Ap [2]-1 = 5**.

To iterate over the columns and entries of this matrix, the following code can be used (assuming it has type **GrB\_FP64**):

```
integer nvals = Ap [ncols] ;
for (integer j = 0 ; j < ncols ; j++)
{
    // get A(:,j)
    for (integer p = Ap [j] ; p < Ap [j+1] ; p++)
    {
        // get A(i,j)
        integer i = Ai [p] ;           // row index
        double aij = Ax [iso ? 0 : p] ; // numerical value
    }
}
```

In the container, the three arrays **Ap**, **Ai** and **Ax** are held in three **GrB\_Vector** objects: **Container->p**, **Container->i**, and **Container->x**, respectively.

### 6.13.3 Hypersparse, held by row

The hypersparse HyperCSR format is identical to the CSR format, except that the **Ap** array itself becomes sparse, if the matrix has rows that are completely empty. An array **Ah** of size **nvec** provides a list of rows that appear in the data structure. For example, consider Equation 3, which is a sparser version of the matrix in Equation 1. Row 2 and column 1 of this matrix are all empty.

$$A = \begin{bmatrix} 4.5 & 0 & 3.2 & 0 \\ 3.1 & 0 & 0 & 0.9 \\ 0 & 0 & 0 & 0 \\ 3.5 & 0 & 0 & 1.0 \end{bmatrix} \quad (3)$$

The conventional CSR format would appear as follows. Since the third row (row 2) is all zero, accessing **Ai** [**Ap** [2] ... **Ap** [3]-1] gives an empty set ([2..1]), and the number of entries in this row is **Ap** [i+1] - **Ap** [i] = **Ap** [3] - **Ap** [2] = 0.

```
integer Ap [ ] = { 0,      2,2,      4,      5 } ;
integer Aj [ ] = { 0,    2,    0,    3,    0    3 } ;
double Ax [ ] = { 4.5, 3.2, 3.1, 0.9, 3.5, 1.0 } ;
```

A hypersparse CSR format for this same matrix would discard these duplicate integers in **Ap**. Doing so requires another array, **Ah**, that keeps track of the rows that appear in the data structure.

```
integer nvec = 3 ;
integer Ah [ ] = { 0,      1,      3      } ;
integer Ap [ ] = { 0,      2,      4,      5 } ;
integer Aj [ ] = { 0,    2,    0,    3,    0    3 } ;
double Ax [ ] = { 4.5, 3.2, 3.1, 0.9, 3.5, 1.0 } ;
```

Note that the **Aj** and **Ax** arrays are the same in the CSR and HyperCSR formats. If **jumbled** is false, the row indices in **Ah** must appear in ascending order, and no duplicates can appear. To iterate over this data structure (assuming it has type **GrB\_FP64**):

```

integer nvals = Ap [nvec] ;
for (integer k = 0 ; k < nvec ; k++)
{
    integer i = Ah [k] ;                // row index
    // get A(i,:)
    for (integer p = Ap [k] ; p < Ap [k+1] ; p++)
    {
        // get A(i,j)
        integer j = Aj [p] ;           // column index
        double aij = Ax [iso ? 0 : p] ; // numerical value
    }
}

```

This is more complex than the CSR format, but it requires at most  $O(e)$  space, where  $A$  is  $m$ -by- $n$  with  $e = \text{nvals}$  entries. The CSR format requires  $O(m + e)$  space. If  $e \ll m$ , then the size  $m + 1$  of  $\text{Ap}$  can dominate the memory required. In the hypersparse form,  $\text{Ap}$  takes on size  $\text{nvec}+1$ , and  $\text{Ah}$  has size  $\text{nvec}$ , where  $\text{nvec}$  is the number of rows that appear in the data structure. The CSR format can be viewed as a dense array (of size  $\text{nrows}$ ) of sparse row vectors. By contrast, the hypersparse CSR format is a sparse array (of size  $\text{nvec}$ ) of sparse row vectors.

In the container, the four arrays  $\text{Ap}$ ,  $\text{Ah}$ ,  $\text{Aj}$  and  $\text{Ax}$  are held in four `GrB_Vector` objects: `Container->p`, `Container->h`, `Container->i`, and `Container->x`, respectively.

In addition, the container may hold an optional optimization structure, `Container->Y`, called the hyper-hash. This is a `GrB_Matrix` that holds the inverse of the `Container->h` array (called  $Y$  because it looks like an upside-down  $h$ ). If a matrix is being loaded from raw data, the hyper-hash is not yet constructed, so the `Container->Y` matrix should be set to `NULL`. GraphBLAS will compute it when needed.

When a matrix is unload into a container, GraphBLAS will place the hyper-hash matrix there if it has been computed. If the matrix is subsequently loaded from the container, and `Container->h` is unchanged, then leaving the hyper-hash unmodified will preserve this optional optimization data structure. If instead `Container->h` is revised, the hyper-hash in `Container->Y` must be freed (or at least removed from the container) when the matrix is loaded from the container..

A `GrB_Vector` is never held in hypersparse format.

#### 6.13.4 Hypersparse, held by column

The hypersparse-by-column format is the transpose of the hypersparse-by-row format. The `Container->format` is `GxB_HYPERSPARSE` and the `Container->orientation` is `GrB_COLMAJOR`. In the container, the four arrays `Ap`, `Ah`, `Ai` and `Ax` are held in four `GrB_Vector` objects: `Container->p`, `Container->h`, `Container->i`, and `Container->x`, respectively. A `GrB_Vector` is never held in hypersparse format.

#### 6.13.5 Bitmap, held by row

The `Container->format` is `GxB_BITMAP` and the `Container->orientation` is `GrB_ROWMAJOR`. This format requires two arrays, `Ab` and `Ax`, each of which are size `nrows*ncols`. They correspond to `Container->b` and `Container->x` in the `GxB_Container` object. These arrays define the pattern and values of the matrix `A`:

- `int8_t Ab [nrows*ncols]` ; The `Ab` array defines which entries of `A` are present. If `Ab[i*ncols+j]=1`, then the entry  $A(i, j)$  is present, with value `Ax[i*ncols+j]`. If `Ab[i*ncols+j]=0`, then the entry  $A(i, j)$  is not present. The `Ab` array must contain only 0s and 1s. The `nvals` input must exactly match the number of 1s in the `Ab` array.
- `type Ax [nrows*ncols]` ; The `Ax` array defines the values of entries in the matrix. If `Ab[p]` is zero, the value of `Ax[p]` is ignored. If the matrix is iso-valued, `Ax` has size 1.

#### 6.13.6 Bitmap, held by column

This is the transpose of the bitmap-by-row format. The `Container->format` is `GxB_BITMAP` and the `Container->orientation` is `GrB_COLMAJOR`. The value of the entry  $A(i, j)$  is held in `Ax [i+j*nrows]`, or in `Ax[0]` if the matrix is iso-valued. It is present if `Ab [i+j*nrows]` is 1, and not present if zero.

#### 6.13.7 Full, held by row

The `Container->format` is `GxB_FULL` and the `Container->orientation` is `GrB_ROWMAJOR`. This format is held in a single `GrB_Vector`, `Container->x`.

The  $A(i, j)$  entry is in position  $i*\text{ncols}+j$  in this array, or in position 0 if the matrix is iso-valued. All entries are present.

#### **6.13.8 Full, held by column**

This is the transpose of the full-by-row format. The `Container->format` is `GxB_FULL` and the `Container->orientation` is `GrB_COLMAJOR`. This format is held in a single `GrB_Vector`, `Container->x`. The  $A(i, j)$  entry is in position  $i+j*\text{nrows}$  in this array, or in position 0 if the matrix is iso-valued. All entries are present.

## 6.14 GraphBLAS import/export: using copy semantics

The v2.0 C API includes import/export methods for matrices (not vectors) using a different strategy as compared to the `GxB_Container` methods. The `GxB_Container` methods are based on *move semantics*, in which ownership of arrays is passed between SuiteSparse:GraphBLAS and the user application. This allows the `GxB_Container` methods to work in  $O(1)$  time, and require no additional memory, but it requires that GraphBLAS and the user application agree on which memory manager to use. This is done via `GxB_init`. This allows GraphBLAS to `malloc` an array that can be later `freed` by the user application, and visa versa.

The `GrB` import/export methods take a different approach. The data is always copied in and out between the opaque GraphBLAS matrix and the user arrays. This takes  $\Omega(e)$  time, if the matrix has  $e$  entries, and requires more memory. It has the advantage that it does not require GraphBLAS and the user application to agree on what memory manager to use, since no ownership of allocated arrays is changed.

The format for `GrB_Matrix_import` and `GrB_Matrix_export` is controlled by the following enum:

```
typedef enum
{
    GrB_CSR_FORMAT = 0,      // CSR format (equiv to GxB_SPARSE with GrB_ROWMAJOR)
    GrB_CSC_FORMAT = 1,     // CSC format (equiv to GxB_SPARSE with GrB_COLMAJOR)
    GrB_COO_FORMAT = 2      // triplet format (like input to GrB*build)
}
GrB_Format ;
```

### 6.14.1 GrB\_Matrix\_import: import a matrix

```
GrB_Info GrB_Matrix_import // import a matrix
(
    GrB_Matrix *A,          // handle of matrix to create
    GrB_Type type,          // type of matrix to create
    GrB_Index nrows,        // number of rows of the matrix
    GrB_Index ncols,        // number of columns of the matrix
    const GrB_Index *Ap,    // pointers for CSR, CSC, column indices for COO
    const GrB_Index *Ai,    // row indices for CSR, CSC
    const <type> *Ax,       // values
    GrB_Index Ap_len,       // number of entries in Ap (not # of bytes)
    GrB_Index Ai_len,       // number of entries in Ai (not # of bytes)
    GrB_Index Ax_len,       // number of entries in Ax (not # of bytes)
    int format              // import format (GrB_Format)
);
```

The `GrB_Matrix_import` method copies from user-provided arrays into an opaque `GrB_Matrix` and `GrB_Matrix_export` copies data out, from an opaque `GrB_Matrix` into user-provided arrays.

The suffix `TYPE` in the prototype above is one of `BOOL`, `INT8`, `INT16`, etc, for built-n types, or `UDT` for user-defined types. The type of the `Ax` array must match this type. No typecasting is performed.

Unlike the `GxB_Container` methods, memory is not handed off between the user application and GraphBLAS. The three arrays `Ap`, `Ai`, and `Ax` are not modified, and are still owned by the user application when the method finishes.

`GrB_Matrix_import` does not support the creation of matrices with 32-bit integer indices.

The matrix can be imported in one of three different formats:

- **GrB\_CSR\_FORMAT**: Compressed-row format. `Ap` is an array of size `nrows+1`. The arrays `Ai` and `Ax` are of size `nvals = Ap[nrows]`, and `Ap[0]` must be zero. The column indices of entries in the `i`th row appear in `Ai[Ap[i]...Ap[i+1]-1]`, and the values of those entries appear in the same locations in `Ax`. The column indices need not be in any particular order. See Section 6.13.1 for details of the sparse-by-row (CSR) format.
- **GrB\_CSC\_FORMAT**: Compressed-column format. `Ap` is an array of size `ncols+1`. The arrays `Ai` and `Ax` are of size `nvals = Ap[ncols]`, and `Ap[0]` must be zero. The row indices of entries in the `j`th column appear in `Ai[Ap[j]...Ap[j+1]-1]`, and the values of those entries

appear in the same locations in `Ax`. The row indices need not be in any particular order. See Section 6.13.2 for details of the sparse-by-column (CSC) format.

- **GrB\_COO\_FORMAT**: Coordinate format. This is the same format as the `I`, `J`, `X` inputs to `GrB_Matrix_build`. The three arrays `Ap`, `Ai`, and `Ax` have the same size. The  $k$ th tuple has row index `Ai[k]`, column index `Ap[k]`, and value `Ax[k]`. The tuples can appear any order, but no duplicates are permitted.

### 6.14.2 GrB\_Matrix\_export: export a matrix

```
GrB_Info GrB_Matrix_export // export a matrix
(
    GrB_Index *Ap,          // pointers for CSR, CSC, column indices for COO
    GrB_Index *Ai,          // col indices for CSR/COO, row indices for CSC
    <type> *Ax,             // values (must match the type of A_input)
    GrB_Index *Ap_len,      // number of entries in Ap (not # of bytes)
    GrB_Index *Ai_len,      // number of entries in Ai (not # of bytes)
    GrB_Index *Ax_len,      // number of entries in Ax (not # of bytes)
    int format,             // export format (GrB_Format)
    GrB_Matrix A            // matrix to export
);
```

`GrB_Matrix_export` copies the contents of a matrix into three user-provided arrays, using any one of the three different formats described in Section 6.14.1. The size of the arrays must be at least as large as the lengths returned by `GrB_Matrix_exportSize`. The matrix `A` is not modified.

On input, the size of the three arrays `Ap`, `Ai`, and `Ax` is given by `Ap_len`, `Ai_len`, and `Ax_len`, respectively. These values are in terms of the number of entries in these arrays, not the number of bytes. On output, these three value are adjusted to report the number of entries written to the three arrays.

The suffix `TYPE` in the prototype above is one of `BOOL`, `INT8`, `INT16`, etc, for built-n types, or `UDT` for user-defined types. The type of the `Ax` array must match this type. No typecasting is performed.

`GrB_Matrix_export` always exports the indices and offsets of the matrix using 64-bit integer indices, even if they are held internally using 32-bit integers.

### 6.14.3 GrB\_Matrix\_exportSize: determine size of export

```
GrB_Info GrB_Matrix_exportSize // determine sizes of user arrays for export
(
    GrB_Index *Ap_len,          // # of entries required for Ap (not # of bytes)
    GrB_Index *Ai_len,          // # of entries required for Ai (not # of bytes)
    GrB_Index *Ax_len,          // # of entries required for Ax (not # of bytes)
    int format,                 // export format (GrB_Format)
    GrB_Matrix A                 // matrix to export
);
```

Returns the required sizes of the arrays Ap, Ai, and Ax for exporting a matrix using GrB\_Matrix\_export, using the same format.

### 6.14.4 GrB\_Matrix\_exportHint: determine best export format

```
GrB_Info GrB_Matrix_exportHint // suggest the best export format
(
    int *format,                // export format (GrB_Format)
    GrB_Matrix A                 // matrix to export
);
```

This method suggests the most efficient format for the export of a given matrix. For SuiteSparse:GraphBLAS, the hint depends on the current format of the GrB\_Matrix:

- GxB\_SPARSE, GrB\_ROWMAJOR: export as GrB\_CSR\_FORMAT
- GxB\_SPARSE, GrB\_COLMAJOR: export as GrB\_CSC\_FORMAT
- GxB\_HYPERSPARSE: export as GrB\_COO\_FORMAT
- GxB\_BITMAP, GrB\_ROWMAJOR: export as GrB\_CSR\_FORMAT
- GxB\_BITMAP, GrB\_COLMAJOR: export as GrB\_CSC\_FORMAT
- GxB\_FULLL, GrB\_ROWMAJOR: export as GrB\_CSR\_FORMAT
- GxB\_FULLL, GrB\_COLMAJOR: export as GrB\_CSC\_FORMAT

## 6.15 Sorting methods

`GxB_Matrix_sort` provides a mechanism to sort all the rows or all the columns of a matrix, and `GxB_Vector_sort` sorts all the entries in a vector.

### 6.15.1 `GxB_Vector_sort`: sort a vector

```
GrB_Info GxB_sort
(
    // output:
    GrB_Vector w,          // vector of sorted values
    GrB_Vector p,          // vector containing the permutation
    // input
    GrB_BinaryOp op,       // comparator op
    GrB_Vector u,          // vector to sort
    const GrB_Descriptor desc
) ;
```

`GxB_Vector_sort` is identical to sorting the single column of an  $n$ -by-1 matrix. Refer to Section 6.15.2 for details. The `op` cannot be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

### 6.15.2 `GxB_Matrix_sort`: sort the rows/columns of a matrix

```
GrB_Info GxB_sort
(
    // output:
    GrB_Matrix C,          // matrix of sorted values
    GrB_Matrix P,          // matrix containing the permutations
    // input
    GrB_BinaryOp op,       // comparator op
    GrB_Matrix A,          // matrix to sort
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_sort` sorts all the rows or all the columns of a matrix. Each row (or column) is sorted separately. The rows are sorted by default. To sort the columns, use `GrB_DESC_T0`. A comparator operator is provided to define the sorting order (ascending or descending). For example, to sort a `GrB_FP64` matrix in ascending order, use `GrB_LT_FP64` as the `op`, and to sort in descending order, use `GrB_GT_FP64`.

The `op` must have a return value of `GrB_BOOL`, and the types of its two inputs must be the same. The entries in `A` are typecasted to the inputs of

the `op`, if necessary. Matrices with user-defined types can be sorted with a user-defined comparator operator, whose two input types must match the type of `A`, and whose output is `GrB_BOOL`.

The two matrix outputs are `C` and `P`. Any entries present on input in `C` or `P` are discarded on output. The type of `C` must match the type of `A` exactly. The dimensions of `C`, `P`, and `A` must also match exactly (even with the `GrB_DESC_T0` descriptor).

With the default sort (by row), suppose `A(i,:)` contains `k` entries. In this case, `C(i,0:k-1)` contains the values of those entries in sorted order, and `P(i,0:k-1)` contains their corresponding column indices in the matrix `A`. If two values are the same, ties are broken according column index.

If the matrix is sorted by column, and `A(:,j)` contains `k` entries, then `C(0:k-1,j)` contains the values of those entries in sorted order, and `P(0:k-1,j)` contains their corresponding row indices in the matrix `A`. If two values are the same, ties are broken according row index.

The outputs `C` and `P` are both optional; either one (but not both) may be `NULL`, in which case that particular output matrix is not computed. The `op` cannot be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

## 6.16 GraphBLAS descriptors: GrB\_Descriptor

A GraphBLAS *descriptor* modifies the behavior of a GraphBLAS operation. If the descriptor is GrB\_NULL, defaults are used.

The access to these parameters and their values is governed by two `enum` types, GrB\_Desc\_Field and GrB\_Desc\_Value:

```
typedef enum
{
    GrB_OUTP = 0,    // descriptor for output of a method
    GrB_MASK = 1,    // descriptor for the mask input of a method
    GrB_INP0 = 2,    // descriptor for the first input of a method
    GrB_INP1 = 3,    // descriptor for the second input of a method
    GxB_AxB_METHOD = 1000, // descriptor for selecting C=A*B algorithm
    GxB_SORT = 35    // control sort in GrB_mxm
    GxB_COMPRESSION = 36, // select compression for serialize
    GxB_ROWINDEX_LIST = 7062, // how GrB_Vector I is interpreted
    GxB_COLINDEX_LIST = 7063, // how GrB_Vector J is interpreted
    GxB_VALUE_LIST = 7064,    // how GrB_Vector X is interpreted
}
GrB_Desc_Field ;

typedef enum
{
    // for all GrB_Descriptor fields:
    GrB_DEFAULT = 0,    // default behavior of the method
    // for GrB_OUTP only:
    GrB_REPLACE = 1,    // clear the output before assigning new values to it
    // for GrB_MASK only:
    GrB_COMP = 2,        // use the complement of the mask
    GrB_STRUCTURE = 4,   // use the structure of the mask
    // for GrB_INP0 and GrB_INP1 only:
    GrB_TRAN = 3,        // use the transpose of the input
    // for GxB_AxB_METHOD only:
    GxB_AxB_GUSTAVSON = 1001, // gather-scatter saxpy method
    GxB_AxB_DOT = 1003,    // dot product
    GxB_AxB_HASH = 1004,   // hash-based saxpy method
    GxB_AxB_SAXPY = 1005   // saxpy method (any kind)
    // for GxB_ROWINDEX_LIST, GxB_COLINDEX_LIST, and GxB_VALUE_LIST:
    // GxB_USE_VALUES = ((int) GrB_DEFAULT) // use the values of the vector
    GxB_USE_INDICES = 7060, // use the indices of the vector
    GxB_IS_STRIDE = 7061,   // use the values, of size 3, for lo:hi:inc
}
GrB_Desc_Value ;
```

- **GrB\_OUTP** is a parameter that modifies the output of a GraphBLAS operation. In the default case, the output is not cleared, and  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$  then  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$  are computed as-is, where  $\mathbf{T}$  is the results of the particular GraphBLAS operation.

In the non-default case,  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$  is first computed, using the results of  $\mathbf{T}$  and the accumulator  $\odot$ . After this is done, if the **GrB\_OUTP** descriptor field is set to **GrB\_REPLACE**, then the output is cleared of its entries. Next, the assignment  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$  is performed.

- **GrB\_MASK** is a parameter that modifies the **Mask**, even if the mask is not present.

If this parameter is set to its default value, and if the mask is not present (**Mask**==NULL) then implicitly **Mask**(*i*,*j*)=1 for all *i* and *j*. If the mask is present then **Mask**(*i*,*j*)=1 means that  $\mathbf{C}(\mathbf{i}, \mathbf{j})$  is to be modified by the  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$  update. Otherwise, if **Mask**(*i*,*j*)=0, then  $\mathbf{C}(\mathbf{i}, \mathbf{j})$  is not modified, even if  $\mathbf{Z}(\mathbf{i}, \mathbf{j})$  is an entry with a different value; that value is simply discarded.

If the **GrB\_MASK** parameter is set to **GrB\_COMP**, then the use of the mask is complemented. In this case, if the mask is not present (**Mask**==NULL) then implicitly **Mask**(*i*,*j*)=0 for all *i* and *j*. This means that none of  $\mathbf{C}$  is modified and the entire computation of  $\mathbf{Z}$  might as well have been skipped. That is, a complemented empty mask means no modifications are made to the output object at all, except perhaps to clear it in accordance with the **GrB\_OUTP** descriptor. With a complemented mask, if the mask is present then **Mask**(*i*,*j*)=0 means that  $\mathbf{C}(\mathbf{i}, \mathbf{j})$  is to be modified by the  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$  update. Otherwise, if **Mask**(*i*,*j*)=1, then  $\mathbf{C}(\mathbf{i}, \mathbf{j})$  is not modified, even if  $\mathbf{Z}(\mathbf{i}, \mathbf{j})$  is an entry with a different value; that value is simply discarded.

If the **GrB\_MASK** parameter is set to **GrB\_STRUCTURE**, then the values of the mask are ignored, and just the pattern of the entries is used. Any entry  $\mathbf{M}(\mathbf{i}, \mathbf{j})$  in the pattern is treated as if it were true.

The **GrB\_COMP** and **GrB\_STRUCTURE** settings can be combined, either by setting the mask option twice (once with each value), or by setting the mask option to **GrB\_COMP+GrB\_STRUCTURE** (the latter is an extension to the specification).

Using a parameter to complement the `Mask` is very useful because constructing the actual complement of a very sparse mask is impossible since it has too many entries. If the number of places in `C` that should be modified is very small, then use a sparse mask without complementing it. If the number of places in `C` that should be protected from modification is very small, then use a sparse mask to indicate those places, and use a descriptor `GrB_MASK` that complements the use of the mask.

- `GrB_INP0` and `GrB_INP1` modify the use of the first and second input matrices `A` and `B` of the GraphBLAS operation.

If the `GrB_INP0` is set to `GrB_TRAN`, then `A` is transposed before using it in the operation. Likewise, if `GrB_INP1` is set to `GrB_TRAN`, then the second input, typically called `B`, is transposed.

Vectors and scalars are never transposed via the descriptor. If a method's first parameter is a matrix and the second a vector or scalar, then `GrB_INP0` modifies the matrix parameter and `GrB_INP1` is ignored. If a method's first parameter is a vector or scalar and the second a matrix, then `GrB_INP1` modifies the matrix parameter and `GrB_INP0` is ignored.

To clarify this in each function, the inputs are labeled as `first input`: and `second input`: in the function signatures.

- `GxB_AxB_METHOD` suggests the method that should be used to compute  $C=A*B$ . All the methods compute the same result, except they may have different floating-point roundoff errors. This descriptor should be considered as a hint; SuiteSparse:GraphBLAS is free to ignore it.
  - `GrB_DEFAULT` means that a method is selected automatically.
  - `GxB_AxB_SAXPY`: select any saxpy-based method: `GxB_AxB_GUSTAVSON`, and/or `GxB_AxB_HASH`, or any mix of the two, in contrast to the dot-product method.
  - `GxB_AxB_GUSTAVSON`: an extended version of Gustavson's method [Gus78], which is a very good general-purpose method, but sometimes the workspace can be too large. Assuming all matrices are stored by column, it computes  $C(:,j)=A*B(:,j)$  with a sequence of *saxpy* operations  $(C(:,j)+=A(:,k)*B(k:,j))$  for each nonzero

$B(k, j)$ ). In the *coarse Gustavson* method, each internal thread requires workspace of size  $m$ , to the number of rows of  $C$ , which is not suitable if the matrices are extremely sparse or if there are many threads. For the *fine Gustavson* method, threads can share workspace and update it via atomic operations. If all matrices are stored by row, then it computes  $C(i, :) = A(i, :) * B$  in a sequence of sparse *saxpy* operations, and using workspace of size  $n$  per thread, or group of threads, corresponding to the number of columns of  $C$ .

- **GxB\_AxB\_HASH**: a hash-based method, based on [NMAB18]. It is very efficient for hypersparse matrices, matrix-vector-multiply, and when  $|B|$  is small. SuiteSparse:GraphBLAS includes a *coarse hash* method, in which each thread has its own hash workspace, and a *fine hash* method, in which groups of threads share a single hash workspace, as concurrent data structure, using atomics.
- **GxB\_AxB\_DOT**: computes  $C(i, j) = A(i, :) * B(j, :)'$ , for each entry  $C(i, j)$ . If the mask is present and not complemented, only entries for which  $M(i, j) = 1$  are computed. This is a very specialized method that works well only if the mask is present, very sparse, and not complemented, when  $C$  is small, or when  $C$  is bitmap or full. For example, it works very well when  $A$  and  $B$  are tall and thin, and  $C \langle M \rangle = A * B'$  or  $C = A * B'$  are computed. These expressions assume all matrices are in CSR format. If in CSC format, then the dot-product method used for  $A' * B$ . The method is impossibly slow if  $C$  is large and the mask is not present, since it takes  $\Omega(mn)$  time if  $C$  is  $m$ -by- $n$  in that case. It does not use any workspace at all. Since it uses no workspace, it can work very well for extremely sparse or hypersparse matrices, when the mask is present and not complemented.
- **GxB\_SORT** provides a hint to **GrB\_mxm**, **GrB\_mxv**, **GrB\_vxm**, and **GrB\_reduce** (to vector). These methods can leave the output matrix or vector in a jumbled state, where the final sort is left as pending work. This is typically fastest, since some algorithms can tolerate jumbled matrices on input, and sometimes the sort can be skipped entirely. However, if the matrix or vector will be immediately exported in unjumbled form, or provided as input to a method that requires it to not be jumbled, then

sorting it during the matrix multiplication is faster. By default, these methods leave the result in jumbled form (a *lazy sort*), if `GxB_SORT` is set to zero (`GrB_DEFAULT`). A nonzero value will inform the matrix multiplication to sort its result, instead.

- `GxB_COMPRESSION` selects the compression method for serialization. The default is ZSTD (level 1). See Section 6.11 for other options.

The next sections describe the methods for a `GrB_Descriptor`:

GraphBLAS function	purpose	Section
<code>GrB_Descriptor_new</code>	create a descriptor	<a href="#">6.16.1</a>
<code>GrB_Descriptor_wait</code>	wait for a descriptor	<a href="#">6.16.2</a>
<code>GrB_Descriptor_free</code>	free a descriptor	<a href="#">6.16.3</a>
<code>GrB_get</code>	get a parameter from a descriptor	<a href="#">10.14</a>
<code>GrB_set</code>	set a parameter in a descriptor	<a href="#">10.14</a>

#### 6.16.1 `GrB_Descriptor_new`: create a new descriptor

```
GrB_Info GrB_Descriptor_new    // create a new descriptor
(
    GrB_Descriptor *descriptor // handle of descriptor to create
) ;
```

`GrB_Descriptor_new` creates a new descriptor, with all fields set to their defaults (output is not replaced, the mask is not complemented, the mask is valued not structural, neither input matrix is transposed, the method used in  $C=A*B$  is selected automatically, and `GrB_mxm` leaves the final sort as pending work).

#### 6.16.2 `GrB_Descriptor_wait`: wait for a descriptor

```
GrB_Info GrB_wait                // wait for a descriptor
(
    GrB_Descriptor descriptor,    // descriptor to wait for
    int mode                     // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

After creating a user-defined descriptor, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS does nothing except to ensure that `d` is valid.

### 6.16.3 GrB\_Descriptor\_free: free a descriptor

```
GrB_Info GrB_free          // free a descriptor
(
    GrB_Descriptor *descriptor // handle of descriptor to free
) ;
```

GrB\_Descriptor\_free frees a descriptor. Either usage:

```
GrB_Descriptor_free (&descriptor) ;
GrB_free (&descriptor) ;
```

frees the `descriptor` and sets `descriptor` to NULL. It safely does nothing if passed a NULL handle, or if `descriptor == NULL` on input.

### 6.16.4 Descriptor settings for GrB\_Vector parameters

Several methods GraphBLAS v10 accept `GrB_Vector` parameters for their index lists `I` and `J`, which appear only as `uint64_t * C` arrays in the v2.1 C Specification. Likewise, several methods accept a `GrB_Vector` parameter `X`, where the related method in the Specification accepts only a raw C array of a given type.

By default, `GrB_Vector` inputs `I`, `J`, and `X` are interpreted as if their values are first extracted with `GrB_Vector_extractTuples`, where the values are extracted in order (with ascending indices), and their values are then passed to the method. The actual method is much faster; GraphBLAS uses the values directly.

This behavior can be revised via the descriptor for the method. Three settings are available:

- `GxB_ROWINDEX_LIST`: how the `GrB_Vector I` is interpreted.
- `GxB_COLINDEX_LIST`: how the `GrB_Vector J` is interpreted.
- `GxB_VALUE_LIST`: how `GrB_Vector X` is interpreted (for `GrB_build` only).

These can be set to one of the following values:

- `GrB_DEFAULT` or `GxB_USE_VALUES`: use the values of the vector (default).

- **GxB\_USE\_INDICES**: use the indices of the vector. This acts as if the indices are first extracted into a C array with **GrB\_Vector\_extractTuples**, where the indices are extracted in ascending order, and then this C array is then passed to the method. The actual method is much faster; GraphBLAS uses the indices directly.
- **GxB\_IS\_STRIDE**: use the values, of size 3, for a strided range, or **lo:inc:hi** in MATLAB notation. This usage is limited to the **I** and **J** vectors (except this option may not be used for **GrB\_build**). The vector must have exactly three entries, **lo**, **hi**, and **inc**, in that order.

The **GxB\_IS\_STRIDE** option is fully described in Section 11. In that section, there are many options available. Here, the **GrB\_Vector** **I** or **J** must have length exactly three. The first entry present is the start of the sequence (**lo**), the second entry is the end of the sequence (**hi**) and the third entry is the stride (**inc**). This corresponds to the **GxB\_STRIDE** option when passing a **uint64\_t \*** array. To use a stride of one, simply set the third entry to 1; this corresponds to the **GxB\_RANGE** option when passing a **uint64\_t \*** array. To use a negative stride, simply pass in the vector with a signed data type (**GrB\_INT32** or **GrB\_INT64** as appropriate; this corresponds to the **GxB\_BACKWARDS** option described in Section 11). These three values appear in this order to be consistent **GxB\_BEGIN** (0), **GxB\_END** (1), and **GxB\_INC** (2).

When using the **\_Vector** methods, the **GrB\_Vector** objects **I**, **J**, and **X** may be sparse. If the vectors are sparse, **GrB\_Vector\_extractTuples** returns a dense list of indices or values, and this is how the **I**, **J**, **X** vectors may be used in the new methods in GraphBLAS v10 with the **\_Vector** suffix at the end of their name.

To use the **GrB\_ALL** option, specifying all the rows or columns of a matrix or all indices of a vector, pass in the corresponding **GrB\_Vector** **I** or **J** as a **NULL** pointer.

### 6.16.5 GrB\_DESC\_\*: built-in descriptors

Built-in descriptors are listed in the table below. A dash in the table indicates the default. These descriptors may not be modified or freed. Attempts to modify them result in an error (GrB\_INVALID\_VALUE); attempts to free them are silently ignored.

Descriptor	OUTP	MASK structural	MASK complement	INP0	INP1

## 6.17 GrB\_free: free any GraphBLAS object

Each of the ten objects has `GrB*_new` and `GrB*_free` methods that are specific to each object. They can also be accessed by a generic function, `GrB_free`, that works for all ten objects. If `G` is any of the ten objects, the statement

```
GrB_free (&G) ;
```

frees the object and sets the variable `G` to `NULL`. It is safe to pass in a `NULL` handle, or to free an object twice:

```
GrB_free (NULL) ;      // SuiteSparse:GraphBLAS safely does nothing
GrB_free (&G) ;        // the object G is freed and G set to NULL
GrB_free (&G) ;        // SuiteSparse:GraphBLAS safely does nothing
```

However, the following sequence of operations is not safe. The first two are valid but the last statement will lead to undefined behavior.

```
H = G ;                // valid; creates a 2nd handle of the same object
GrB_free (&G) ;        // valid; G is freed and set to NULL; H now undefined
GrB_some_method (H) ;   // not valid; H is undefined
```

Some objects are predefined, such as the built-in types. If a user application attempts to free a built-in object, SuiteSparse:GraphBLAS will safely do nothing. The `GrB_free` function in SuiteSparse:GraphBLAS always returns `GrB_SUCCESS`.

## 7 The mask, accumulator, and replace option

After a GraphBLAS operation computes a result  $\mathbf{T}$ , (for example,  $\mathbf{T} = \mathbf{AB}$  for `GrB_mxm`), the results are assigned to an output matrix  $\mathbf{C}$  via the mask/accumulator phase, written as  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$ . This phase is affected by the `GrB_REPLACE` option in the descriptor, the presence of an optional binary accumulator operator ( $\odot$ ), the presence of the optional mask matrix  $\mathbf{M}$ , and the status of the mask descriptor. The interplay of these options is summarized in Table 1.

The mask  $\mathbf{M}$  may be present, or not. It may be structural or valued, and it may be complemented, or not. These options may be combined, for a total of 8 cases, although the structural/valued option has no effect if  $\mathbf{M}$  is not present. If  $\mathbf{M}$  is not present and not complemented, then  $m_{ij}$  is implicitly true. If not present yet complemented, then all  $m_{ij}$  entries are implicitly zero; in this case,  $\mathbf{T}$  need not be computed at all. Either  $\mathbf{C}$  is not modified, or all its entries are cleared if the replace option is enabled. If  $\mathbf{M}$  is present, and the structural option is used, then  $m_{ij}$  is treated as true if it is an entry in the matrix (its value is ignored). Otherwise, the value of  $m_{ij}$  is used. In both cases, entries not present are implicitly zero. These values are negated if the mask is complemented. All of these various cases are combined to give a single effective value of the mask at position  $ij$ .

The combination of all these options are presented in the Table 1. The first column is the `GrB_REPLACE` option. The second column lists whether or not the accumulator operator is present. The third column lists whether or not  $c_{ij}$  exists on input to the mask/accumulator phase (a dash means that it does not exist). The fourth column lists whether or not the entry  $t_{ij}$  is present in the result matrix  $\mathbf{T}$ . The mask column is the final effective value of  $m_{ij}$ , after accounting for the presence of  $\mathbf{M}$  and the mask options. Finally, the last column states the result of the mask/accum step; if no action is listed in this column, then  $c_{ij}$  is not modified.

Several important observations can be made from this table. First, if no mask is present (and the mask-complement descriptor option is not used), then only the first half of the table is used. In this case, the `GrB_REPLACE` option has no effect. The entire matrix  $\mathbf{C}$  is modified.

Consider the cases when  $c_{ij}$  is present but  $t_{ij}$  is not, and there is no mask or the effective value of the mask is true for this  $ij$  position. With no accumulator operator,  $c_{ij}$  is deleted. If the accumulator operator is present and the replace option is not used,  $c_{ij}$  remains unchanged.

repl	accum	<b>C</b>	<b>T</b>	mask	action taken by $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$

Table 1: Results of the mask/accumulator phase.

When there is no mask and the mask `GrB_COMP` option is not selected, the table simplifies (Table 2). The `GrB_REPLACE` option no longer has any effect. The `GrB_SECOND_T` binary operator when used as the accumulator unifies the first cases, shown in Table 3. The only difference now is the behavior when  $c_{ij}$  is present but  $t_{ij}$  is not. Finally, the effect of `GrB_FIRST_T` as the accumulator is shown in Table 4.

## 8 GxB\_Context: controlling computational resources

SuiteSparse:GraphBLAS v8.0.0 adds a new object, the `GxB_Context`, which controls the number of threads used by OpenMP. In the future, this same object will control the number of GPUs used.

The `GxB_Context` object is not needed if the user application is itself single threaded, with all parallelism is inside GraphBLAS itself. The object is also not needed if the user application is multi-threaded, but all user threads create the same number of threads inside GraphBLAS (say each using a single thread). In that case, `GrB_set(GrB_GLOBAL, 1, GxB_NTHREADS)` can be used (for example).

However, suppose the user application creates 5 threads of its own, on a machine with 16 cores, and each thread wants to use a different number of threads inside GraphBLAS (one user thread uses 8 OpenMP threads and the the other four use 2 each, for example). This is where the `GxB_Context` object becomes essential.

The default context is `GxB_CONTEXT_WORLD`, which is not created by the user application but it can be modified. If a user thread does not create its own context, then its computational resources are determine by this `GxB_CONTEXT_WORLD` object. The following `GrB_set/get` methods access this global object without naming it directly (where `chunk` is a `GrB_Scalar` of type `GrB_FP64` or `GrB_FP32`):

- `GrB_set (GrB_GLOBAL, nthreads, GxB_NTHREADS)`
- `GrB_get (GrB_GLOBAL, &nthreads, GxB_NTHREADS)`
- `GrB_set (GrB_GLOBAL, chunk, GxB_CHUNK)`
- `GrB_get (GrB_GLOBAL, chunk, GxB_CHUNK)`

The above methods control the OpenMP threads used by all user threads in the user application. To allow each user thread to control its own OpenMP threading, each user thread needs to create its own Context object via `GxB_Context_new`. Next, the user thread must *engage* this context via `GxB_Context_engage`; all subsequent calls to GraphBLAS from this particular user thread will then use the number of OpenMP threads dictated by this particular context.

*Engaging* a `GxB_Context` object assigns to a `threadprivate` space accessible only by this particular user thread, so that any calls to GraphBLAS can access the settings in this object.

The opposite operation is to *disengage* a context. This removes a particular object from the `threadprivate` space of the user thread that is disengaging its context.

After a context object is created, the user thread that owns it can modify its settings in this object. An example appears in the `GraphBLAS/Demo` folder, part of which is listed below.

```
#pragma omp parallel for num_threads (nouter) schedule (dynamic, 1)
for (int k = 0 ; k < nmat ; k++)
{
    // each user thread constructs its own context
    GxB_Context Context = NULL ;
    GxB_Context_new (&Context) ;
    GrB_set (Context, ninner, GxB_NTHREADS) ;
    GxB_Context_engage (Context) ;

    // kth user thread builds kth matrix with ninner threads
    GrB_Matrix A = NULL ;
    GrB_Matrix_new (&A, GrB_FP64, n, n) ;
    GrB_Matrix_build (A, I, J, X, nvals, GrB_PLUS_FP64) ;

    // free the matrix just built
    GrB_Matrix_free (&A) ;

    // each user thread frees its own context
    GxB_Context_disengage (Context) ;
    GxB_Context_free (&Context) ;
}
```

In this example, `nouter` user threads are created. Inside the parallel loop, each user thread creates and engages its own context object. In this simple example, each user thread then uses `ninner` threads to do some work, although in principle each user thread to request a different number of threads for each of its calls to GraphBLAS. This leads to nested parallelism, so to use this context object effectively, the nested parallelism feature of OpenMP must be enabled.

The next sections describe the methods for a `GxB_Context`:

GraphBLAS function	purpose	Section
<code>GxB_Context_new</code>	create a context	<a href="#">8.1</a>
<code>GxB_Context_engage</code>	engage a context	<a href="#">8.2</a>
<code>GxB_Context_disengage</code>	disengage a context	<a href="#">8.3</a>
<code>GxB_Context_free</code>	free a context	<a href="#">8.4</a>
<code>GxB_Context_wait</code>	wait for a context	<a href="#">8.5</a>
<code>GrB_get</code>	get a value from a context	<a href="#">10.15</a>
<code>GrB_set</code>	set a value in a context	<a href="#">10.15</a>
<code>GxB_Context_fprint</code>	check/print a context	<a href="#">13.11</a>

## 8.1 `GxB_Context_new`: create a new context

```
GrB_Info GxB_Context_new      // create a new context
(
    GxB_Context *Context      // handle of context to create
);
```

A new context is created and initialized with the current global settings for `GxB_NTHREADS` and `GxB_CHUNK`. See `GrB_get`. The context object will not have an effect on any calls to GraphBLAS until it is *engaged* by a user thread.

## 8.2 `GxB_Context_engage`: engaging context

```
GrB_Info GxB_Context_engage   // engage a Context
(
    GxB_Context Context       // Context to engage
);
```

`GxB_Context_engage` sets the provided Context object as the Context for this user thread. Multiple user threads can share a single Context. Any prior Context for this user thread is superseded by the new Context (the prior one is not freed). `GrB_SUCCESS` is returned, and future calls to GraphBLAS by this user thread will use the provided Context.

If the Context on input is the `GxB_CONTEXT_WORLD` object, then the current Context is disengaged. That is, the following calls have the same effect, setting the Context of this user thread to `GxB_CONTEXT_WORLD`:

```
GxB_Context_engage (GxB_CONTEXT_WORLD) ;
GxB_Context_disengage (NULL) ;
```

The result for both cases above is `GrB_SUCCESS`.

Error cases: If `Context` is `NULL` on input, `GrB_NULL_POINTER` is returned. If a non-`NULL` Context is provided but it is faulty in some way, then an error code is returned (`GrB_INVALID_OBJECT` or `GrB_UNINITIALIZED_OBJECT`). If an error code is returned, the current Context for this user thread is unmodified.

### 8.3 `GxB_Context_disengage`: disengaging context

```
GrB_Info GxB_Context_disengage    // disengage a Context
(
    GxB_Context Context           // Context to disengage
) ;
```

If a `NULL` Context is provided or if the Context input parameter is `GxB_CONTEXT_WORLD`, then any current Context for this user thread is disengaged. If a valid non-`NULL` Context is provided and it matches the current Context for this user thread, it is disengaged. In all of these cases, `GrB_SUCCESS` is returned. The user thread has no Context object and any subsequent calls to GraphBLAS functions will use the world Context, `GxB_CONTEXT_WORLD`.

Error cases: If a non-`NULL` Context is provided but it is faulty in some way, then an error code is returned (`GrB_INVALID_OBJECT` or `GrB_UNINITIALIZED_OBJECT`). If a non-`NULL` Context is provided on input that doesn't match the current Context for this thread, then `GrB_INVALID_VALUE` is returned. If an error code is returned, the current Context for this user thread is unmodified.

### 8.4 `GxB_Context_free`: free a context

```
GrB_Info GrB_free                // free a context
(
    GxB_Context *Context          // handle of Context to free
) ;
```

`GxB_Context_free` frees a descriptor. Either usage:

```
GxB_Context_free (&Context) ;
GrB_free (&Context) ;
```

frees the `Context` and sets `Context` to `NULL`. It safely does nothing if passed a `NULL` handle, or if `Context == NULL` on input.

## 8.5 GxB\_Context\_wait: wait for a context

```
GrB_Info GrB_wait          // wait for a context
(
    GxB_Context Context,    // context to wait for
    int mode                // GrB_COMPLETE or GrB_MATERIALIZE
) ;
```

After creating or modifying a context, a GraphBLAS library may choose to exploit non-blocking mode to delay its creation. Currently, SuiteSparse:GraphBLAS currently does nothing except to ensure that `Context` is valid.

## 9 The SuiteSparse:GraphBLAS JIT

SuiteSparse:GraphBLAS v8.0 adds a new JIT feature that greatly improves performance of user-defined types and operators, and improves the performance of built-in operators as well. The JIT can compile kernels that are specific to the matrix type and the operators that work on it. In version v7.4.4 and prior versions, user-defined types and operators were handled by *generic* kernels that used function pointers for each operator and for any type-casting required. Even built-in types and operators were sometimes handled by the generic kernels, if any typecasting was done, or if the specific operator, monoid, or semiring was disabled when GraphBLAS was compiled.

### 9.1 Using the JIT

Using the JIT in a user application is simple: by default, there is nothing to do. The current release, LAGraph v1.1.4, can use the JIT (and PreJIT) kernels without changing a single line of code.

Currently, the JIT compiles kernels for the CPU only, but a CUDA JIT is in progress to exploit NVIDIA GPUs, in collaboration with Joe Eaton and Corey Nolet, with NVIDIA.

When GraphBLAS is compiled, the `cmake` build system creates a *cache* folder where it will keep any kernels created and compiled by the JIT (both source code and compiled libraries for each kernel). The default folder is `~/.SuiteSparse/GrB8.0.0` for SuiteSparse:GraphBLAS version v8.0.0, where the tilde refers to the user's home directory. The version numbers in the folder name are set automatically, so that a new version will ignore kernels compiled by an older version of GraphBLAS. If the `GRAPHBLAS_CACHE_PATH` environment variable is set when GraphBLAS is compiled, that variable defines the folder. If the user's home directory cannot be determined and the `GRAPHBLAS_CACHE_PATH` environment variable is not set, then JIT compilation is disabled and only PreJIT kernels can be used. The optional environment variable, `GRAPHBLAS_CACHE_PATH`, is also read by `GrB_init` when the user application runs. The filesystem holding the cache folder must also support file locking. See Section 9.1.11 for a description of the valid characters that can appear in the cache path and for more suggestions about file locking.

The user application can modify the location of the cache folder after calling `GrB_init`. It can also modify the C compiler and its flags, and can

control when and how the JIT is used. These changes are made via `GrB_set`, and can be queried via `GrB_get`; refer to Section 10 for details, and the `GxB_JIT_*` settings:

field	value	description
<code>GxB_JIT_C_COMPILER_NAME</code>	<code>char *</code>	C compiler for JIT kernels
<code>GxB_JIT_C_COMPILER_FLAGS</code>	<code>char *</code>	flags for the C compiler
<code>GxB_JIT_C_LINKER_FLAGS</code>	<code>char *</code>	link flags for the C compiler
<code>GxB_JIT_C_LIBRARIES</code>	<code>char *</code>	libraries to link against (no cmake)
<code>GxB_JIT_C_CMAKE_LIBS</code>	<code>char *</code>	libraries to link against (with cmake)
<code>GxB_JIT_C_PREFACE</code>	<code>char *</code>	C code as preface to JIT kernels
<code>GxB_JIT_C_CONTROL</code>	see below	CPU JIT control
<code>GxB_JIT_USE_CMAKE</code>	see below	CPU JIT control
<code>GxB_JIT_ERROR_LOG</code>	<code>char *</code>	error log file
<code>GxB_JIT_CACHE_PATH</code>	<code>char *</code>	folder with compiled kernels

To control the JIT in the MATLAB `@GrB` interface, use the `GrB.jit` method. Refer to `help GrB.jit` for details.

Kernels compiled during one run of a user application are kept in the cache folder, so that when the user application runs again, the kernels do not have to be compiled. If the kernel relies on user-defined types and/or operators, a check is made the first time the compiled kernel is loaded. If the current definition of the user-defined type or operator does not exactly match the definition when the kernel was compiled, then the compiled kernel is discarded and recompiled. The stale kernel is overwritten with the new one, so there is no need to for the user to take any action to delete the stale kernel from the cache path. If the cache path is changed via `GrB_set`, compiled kernels in the old cache folder are not copied over. New ones are compiled instead.

### 9.1.1 `GxB_JIT_C_CONTROL`

The usage of the CPU JIT can be controlled via `GrB_get/set` using the `GxB_JIT_C_CONTROL` setting. If the JIT is enabled at compile time, the initial setting is `GxB_JIT_ON`. If the JIT is disabled at compile time (by setting the cmake variable `GRAPHBLAS_USE_JIT` to `OFF`), the initial setting is `GxB_JIT_RUN`, so that any PreJIT kernels can be run. This setting can be modified; for example to disable the JIT and clear all loaded JIT kernels from memory, use:

```
GrB_set (GrB_GLOBAL, GxB_JIT_OFF, GxB_JIT_C_CONTROL) ;
```

The above call to `GrB_set` does not clear any PreJIT kernels, however, since those are integral components of the single compiled GraphBLAS library and cannot be cleared (see Section 9.3). It also does not clear any compiled user functions, created by the JIT for `GxB_*Op_new` when the input function pointer is `NULL`.

The following settings are available for `GxB_JIT_C_CONTROL`. For examples on how to use it, see `GraphBLAS/Demo/Program/gauss_demo.c`.

```
typedef enum
{
    GxB_JIT_OFF = 0,    // do not use the JIT: free all JIT kernels if loaded
    GxB_JIT_PAUSE = 1,  // do not run JIT kernels but keep any loaded
    GxB_JIT_RUN = 2,    // run JIT kernels if already loaded; no load/compile
    GxB_JIT_LOAD = 3,   // able to load and run JIT kernels; may not compile
    GxB_JIT_ON = 4,     // full JIT: able to compile, load, and run
}
GxB_JIT_Control ;
```

If the JIT is disabled at compile time via setting the `GRAPHBLAS_USE_JIT` option `OFF`, PreJIT kernels are still available, and can be controlled via the `GxB_JIT_OFF`, `GxB_JIT_PAUSE`, or `GxB_JIT_RUN` settings listed above. If the application tries to set the control to `GxB_JIT_LOAD` or `GxB_JIT_ON`, the setting is changed to `GxB_JIT_RUN` instead. This is not an error condition. The resulting setting can be queried via `GrB_get`, if desired.

If your copy of GraphBLAS has many PreJIT kernels compiled into it, or uses many run-time JIT kernels, turning of the JIT with `GxB_JIT_OFF` can be costly. This setting clears the entire JIT hash table. Renabling the JIT and using it will require the JIT table to be repopulated, including a check of each PreJIT kernel the first time they are used. If you wish to temporarily disable the JIT, consider switching the JIT control to `GxB_JIT_PAUSE` and then back to `GxB_JIT_RUN` to reenabling the JIT.

### 9.1.2 JIT error handling

The JIT control setting can be changed by GraphBLAS itself, based on following error conditions. These changes affect all kernels, not just the kernel causing the error. If any of these cases occur, the call to GraphBLAS returns `GxB_JIT_ERROR`, unless GraphBLAS runs out of memory, in which case it returns `GrB_OUT_OF_MEMORY` instead. If the JIT is disabled through any of these errors, it can be detected by `GrB_get` to read the `GxB_JIT_C_CONTROL` state.

- When a kernel is loaded that relies on user-defined types and/or operators, the definitions in the previously compiled kernel are checked against the current definitions. If they do not match, the old one is discarded, and a new kernel will be compiled. However, if the control is set to `GxB_JIT_LOAD`, no new kernels may be compiled. To avoid a continual reloading and checking of stale kernels, the control is changed from `GxB_JIT_LOAD` to `GxB_JIT_RUN`. To solve this problem, delete the compiled kernel with the stale definition, or enable the full JIT by setting the control to `GxB_JIT_ON` so that the kernel can be recompiled with the current definitions.
- If a new kernel is to be compiled with the control set to `GxB_JIT_ON` but the source file cannot be created in the cache folder, or a compiler error occurs, further compilation is disabled. The control is changed from `GxB_JIT_ON` to `GxB_JIT_LOAD`. To solve this problem, make sure your application has write permission to the cache path and that any user-defined types and operators are defined properly so that no syntax error is detected by the compiler.
- If a kernel is loaded but the lookup of the kernel function itself in the compiled library fails, the control is changed to `GxB_JIT_RUN` to prevent this error from occurring again. To solve this problem, delete the corrupted compiled kernel from the cache folder. This case is unlikely to occur since no user action can trigger it. It could indicate a system problem with loading the kernel, or some kind of compiler error that allows the kernel to be compiled but not loaded.
- If an out-of-memory condition occurs in the JIT, the JIT control is set to `GxB_JIT_PAUSE`. This condition is not likely since the JIT does not use a lot of memory.

As a result of this automatic change in the JIT control setting, after the first JIT error is returned, subsequent calls to GraphBLAS will likely succeed. GraphBLAS will use a generic kernel instead. To re-enable the JIT for subsequent calls to GraphBLAS, the user application must reset the `GxB_JIT_C_CONTROL` back to `GxB_JIT_ON`.

In many use cases of GraphBLAS (such as LAGraph), a function will create a type or operator, use it, and then free it just before returning. It would be far too costly to clear the loaded kernel and reload it each time the

LAGraph function is called, so any kernels that use this type or operator are kept loaded when the type or operator is freed. The typical case is that when the LAGraph function is called again, it will recreate the type or operator with the identical name and definition. The kernels that use these types or operators will still be loaded and can thus be used with no overhead.

However, if a user-defined type or operator is freed and then redefined with the same name but a different definition, any loaded kernels should be freed. This case is not detected by GraphBLAS since it would be far too costly to check each time a previously loaded kernel is called. As a result, this condition is only checked when the kernel is first loaded. To avoid this issue, if the user application frees a user-defined type or operator and creates a new one with a different definition but with the same name, clear all prior kernels by setting the control to `GxB_JIT_OFF`. Then turn the JIT back on with `GxB_JIT_ON`. This clears all run-time JIT kernels so that they will be checked when reloaded, and recompiled if their definitions changed. All PreJIT kernels are flagged as unchecked, just as they were flagged by `GrB_init`, so that they will be checked the next time they run.

### 9.1.3 `GxB_JIT_C_COMPILER_NAME`

The `GxB_JIT_C_COMPILER_NAME` string is the name of the C compiler to use, or its full path. By default it is set to the C compiler used to compile GraphBLAS itself.

### 9.1.4 `GxB_JIT_C_COMPILER_FLAGS`

The `GxB_JIT_C_COMPILER_FLAGS` string is the C compiler flags. By default it is set to the C compiler flags used to compile GraphBLAS itself.

### 9.1.5 `GxB_JIT_C_LINKER_FLAGS`

The `GxB_JIT_C_LINKER_FLAGS` string only affects the kernel compilation when cmake is not used to compile the kernels (see Section 9.1.9). By default it is set to the C link flags used to compile GraphBLAS itself. If cmake is used to compile the kernels, then it determines the linker flags itself, and this cannot be modified.

### 9.1.6 GxB\_JIT\_C\_LIBRARIES

The `GxB_JIT_C_LIBRARIES` string is used to set the libraries to link against when `cmake` is not being used to compile the kernels (see Section 9.1.9). For example, on Linux it is set by default to the `-lm`, `-ld`, and OpenMP libraries used to link GraphBLAS itself. Any standalone library name is prepended with `-l`. If `cmake` is used to compile the kernels, this string is ignored.

### 9.1.7 GxB\_JIT\_C\_CMAKE\_LIBS

The `GxB_JIT_C_LIBRARIES` string is used to set the libraries to link against when `cmake` is being used to compile the kernels (see Section 9.1.9). For example, on Linux it is set by default to the `m`, `dl`, and OpenMP libraries used to link GraphBLAS itself. Libraries in the string should normally be separated by semicolons. If `cmake` is not used to compile the kernels, this string is ignored.

### 9.1.8 GxB\_JIT\_C\_PREFACE

The `GxB_JIT_C_PREFACE` string is added at the top of each JIT kernel. It is useful for providing additional `#include` files that GraphBLAS does not provide. It can also be useful for diagnostics and for configuring the `PreJIT`. For example, suppose you wish to tag specific kernels as having been constructed for particular parts of an application. The application can modify this string to some unique comment, and then run some benchmarks that call GraphBLAS. Any JIT kernels created will be tagged with this unique comment, which may be helpful to select specific kernels to copy into the `PreJIT` folder.

### 9.1.9 GxB\_JIT\_USE\_CMAKE

Two methods are provided for compiling the JIT kernels: `cmake`, and a direct compiler/link command. On Windows, only `cmake` may be used, and this setting is ignored (it is always true). On Linux or Mac, the default is false since a direct compile/link is faster. However, it is possible that some compilers are not handled properly with this method, so `cmake` can also be used on those platforms by setting the value of `GxB_JIT_USE_CMAKE` to true.

Normally the same version of `cmake` should be used to compile both GraphBLAS and the JIT kernels. However, compiling GraphBLAS itself

requires cmake v3.16 or later (v3.19 for some options), while compiling the JIT kernels only requires cmake v3.13 or later.

#### 9.1.10 GxB\_JIT\_ERROR\_LOG

The `GxB_JIT_ERROR_LOG` string is the filename of the optional error log file. By default, this string is empty, which means that any compiler errors are routed to the `stderr` output of the user process. If set to a non-empty string, any compiler errors are appended to this file. The string may be `NULL`, which means the same as an empty string.

#### 9.1.11 GxB\_JIT\_CACHE\_PATH

The `GxB_JIT_CACHE_PATH` string is the full path to the user's cache folder (described above). The default on Linux/Mac is `~/.SuiteSparse/GrB8.0.0` for GraphBLAS version 8.0.0. On Windows, the cache folder is created inside the user's `LOCALAPPDATA` folder, called `SuiteSparse/GrB8.0.0`. When GraphBLAS starts, `GrB_init` checks if the `GRAPHBLAS_CACHE_PATH` environment variable exists, and initializes the cache path with that value instead of using the default.

**Restrictions:** the cache path is sanitized for security reasons. No spaces are permitted. Backslashes are converted into forward slashes. It can contain only characters in the following list:

```
abcdefghijklmnopqrstuvwxyz
ABCDEFGHIJKLMNOPQRSTUVWXYZ
0123456789.-_/_
```

In addition, the second character in the string is allowed to be the colon character (`:`) to allow for the use of Windows drive letters. Any character outside of these rules is converted into an underscore (`_`).

On distributed file systems that do not support file locking, sometimes the `/tmp` directory is located on a file system that is not distributed, and is thus suitable to use for the GraphBLAS JIT cache. In this case, try creating a symbolic link in your home file folder (for Linux or Mac):

```
cd
ln -s /tmp/me/.SuiteSparse
```

where `me` is your user name. Next, in your startup script (`.bashrc` for example), add these commands:

```
mkdir /tmp/me
mkdir /tmp/me/.SuiteSparse
```

Then whenever you log into a system that has your home file folder on a distributed file system, the default `~/SuiteSparse` cache folder will be a symbolic link to a folder on a file system that does support file locking.

## 9.2 Compilation options: GRAPHBLAS\_USE\_JIT and GRAPHBLAS\_COMPACT

The CPU JIT can be disabled at compile time by setting the `GRAPHBLAS_USE_JIT` option `OFF` in the `cmake` build options. Good performance will be obtained only by using the `FactoryKernels` or the `PreJIT` kernels that are compiled into GraphBLAS when it is first compiled with `cmake`. By default, `GRAPHBLAS_USE_JIT` is `ON`, to enable the CPU JIT.

With the introduction of the JIT kernels, it is now possible to obtain good performance in GraphBLAS without compiling the many *factory kernels* that appear in the `GraphBLAS/Source/FactoryKernels` directory. If the JIT is enabled, GraphBLAS will still be fast, once the JIT kernels are compiled, or by using any `PreJIT` kernels. To compile GraphBLAS without its `FactoryKernels`, enable the `COMPACT` option in the `cmake` build options. By default, `COMPACT` is off, to enable the `FactoryKernels`.

When GraphBLAS is compiled with `GRAPHBLAS_USE_JIT` set to `OFF`, the `GxB_JIT_C_CONTROL` may be set to `GxB_JIT_OFF`, `GxB_JIT_PAUSE`, or `GxB_JIT_RUN`. No kernels will be loaded at run-time (the `GxB_JIT_LOAD` setting is disabled and treated as `GxB_JIT_RUN`), and no new kernels will be compiled at run-time (the `GxB_JIT_ON` is disabled and treated as `GxB_JIT_RUN`). Only pre-existing `PreJIT` kernels can be run, described in Section 9.3.

If both `GRAPHBLAS_USE_JIT` is set `OFF` and `GRAPHBLAS_COMPACT` is set `ON`, all features of GraphBLAS will be functional. The only fast kernels available will be the `PreJIT` kernels (if any). Otherwise, generic kernels will be used, in which every single operator is implemented with a function pointer, and every scalar assignment requires a `memcpy`. Generic kernels are slow, so using this combination of options is not recommended when preparing GraphBLAS for production use, benchmarking, or for a Linux distro or other widely-used

distribution, unless you are able to run your application in advance and create all the JIT kernels you need, and then copy them into `GraphBLAS/PreJIT`. This would be impossible to do for a general-purpose case such as a Linux distro, but feasible for a more targetted application such as FalkorDB.

### 9.3 Adding PreJIT kernels to GraphBLAS

When GraphBLAS runs, it constructs JIT kernels in the user's cache folder, which by default is `~/.SuiteSparse/GrB8.0.0` for v8.0.0. The kernels placed in a subfolder (`c`) and inside that folder they are further subdivided arbitrarily into subfolders (via an arbitrary hash). The files are split into subfolders because a single folder may grow too large for efficient access. Once GraphBLAS has generated some kernels, some or all of them kernels can then be incorporated into the compiled GraphBLAS library by copying them into the `GraphBLAS/PreJIT` folder. Be sure to move any `*.c` files into the single `GraphBLAS/PreJIT` folder; do not keep the subfolder structure.

If GraphBLAS is then recompiled via `cmake`, the build system will detect these kernels, compile them, and make them available as pre-compiled JIT kernels. The kernels are no longer “Just-In-Time” kernels since they are not compiled at run-time. They are referred to as `PreJIT` kernels since they were at one time created at run-time by the GraphBLAS JIT, but are now compiled into GraphBLAS before it runs.

**It's that simple.** Just copy the source files for any kernels you want from your cache folder (typically `~/.SuiteSparse/GrB8.0.0/c`) into `GraphBLAS/PreJIT`, and recompile GraphBLAS. There's no need to change any other `cmake` setting, and no need to do anything different in any applications that use GraphBLAS. Do not copy the compiled libraries; they are not needed and will be ignored. Just copy the `*.c` files.

If the resulting GraphBLAS library is installed for system-wide usage (say in a Linux distro, Python, RedisGraph, FalkorDB, etc), the `GraphBLAS/PreJIT` kernels will be available to all users of that library. They are not disabled by the `GRAPHBLAS_USE_JIT` option.

Once these kernels are moved to `GraphBLAS/PreJIT` and GraphBLAS is recompiled, they can be deleted from the cache folder. However, even if they are left there, they will not be used since GraphBLAS will find these kernels as `PreJIT` kernels inside the compiled library itself (`libgraphblas.so` on Linux, `libgraphblas.dylib` on the Mac). GraphBLAS will not be any slower if these kernels are left in the cache folder, and the compiled library

size will not be affected.

If the GraphBLAS version is changed at all (even in the last digit), all `GB_jit_*.c` files in the `GraphBLAS/PreJIT` folder should be deleted. The version mismatch will be detected during the call to `GrB_init`, and any stale kernels will be safely ignored. Likewise, if a user-defined type or operator is changed, the relevant kernels should also be deleted from `GraphBLAS/PreJIT`. For example, the `GraphBLAS/Demo/Program/gauss_demo.c` program creates a user-defined `gauss` type, and two operators, `addgauss` and `multgauss`. It then intentionally changes one of the operators just to test this feature. If the type and/or operators are changed, then the `*gauss*.c` files in the `GraphBLAS/PreJIT` folder should be deleted.

GraphBLAS will safely detect any stale `PreJIT` kernels by checking them the first time they are run after calling `GrB_init` and will not use them if they are found to be stale. If the JIT control is set to `GxB_JIT_OFF` all `PreJIT` kernels are flagged as unchecked. If the JIT is then reenabled by setting the control to `GxB_JIT_RUN` or `GxB_JIT_ON`, all `PreJIT` kernels will be checked again and any stale kernels will be detected.

If a stale `PreJIT` kernel is found, GraphBLAS will use its run-time JIT to compile new ones with the current definitions, or it will punt to a generic kernel if JIT compilation is disabled. GraphBLAS will be functional, and fast if it can rely on a JIT kernel, but the unusable stale `PreJIT` kernels take up space inside the compiled GraphBLAS library. The best practice is to delete any stale kernels from the `GraphBLAS/PreJIT` folder, or replace them with newly compiled JIT kernels from the cache folder, and recompile GraphBLAS.

It is safe to copy only a subset of the JIT kernels from the cache folder into `GraphBLAS/PreJIT`. You may also delete any files in `GraphBLAS/PreJIT` and recompile GraphBLAS without those kernels. If GraphBLAS encounters a need for a particular kernel that has been removed from `GraphBLAS/PreJIT`, it will create it at run-time via the JIT, if permitted. If not permitted, by either compiling GraphBLAS with the `GRAPHBLAS_USE_JIT` option set to `OFF`, or by using `GxB_JIT_C_CONTROL` at run-time, the factory kernel or generic kernel will be used instead. The generic kernel will be slower than the `PreJIT` or JIT kernel, but GraphBLAS will still be functional.

In addition to a single `README.txt` file, the `GraphBLAS/PreJIT` folder includes a `.gitignore` file that prevents any files in the folder from being synced via `git`. If you wish to add your `PreJIT` kernels to a fork of GraphBLAS, you will need to revise this `.gitignore` file.

## 9.4 JIT and PreJIT performance considerations

To create a good set of PreJIT kernels for a particular user application, it is necessary to run the application with many different kinds of workloads. Each JIT or PreJIT kernel is specialized to the particular matrix format, data type, operators, and descriptors of its inputs. GraphBLAS can change a matrix format (from sparse to hypersparse, for example), at its discretion, thus triggering the use of a different kernel. Some GraphBLAS methods use heuristics to select between different methods based upon the sparsity structure or estimates of the kind or amount of work required. In these cases, entirely different kernels will be compiled. As a result, it's very difficult to predict which kernels GraphBLAS will find the need to compile, and thus a wide set of test cases should be used in an application to allow GraphBLAS to generate as many kernels as could be expected to appear in production use.

GraphBLAS can encounter very small matrices, and it will often select its bitmap format to store them. This change of format will trigger a different kernel than the sparse or hypersparse cases. There are many other cases like that where specific kernels are only needed for small problems. In this case, compiling an entirely new kernel is costly, since using a compiled kernel will be no faster than the generic kernel. When benchmarking an application to allow GraphBLAS to compile its JIT kernels, it may be useful to pause the JIT via `GxB_JIT_PAUSE`, `GxB_JIT_RUN`, or `GxB_JIT_LOAD`, when the application knows it is calling GraphBLAS for tiny problems. These three settings keep any loaded JIT kernels in memory, but pauses the compilation of any new JIT kernels. Then the control can be reset to `GxB_JIT_ON` once the application finishes with its tiny problems and moves to larger ones where the JIT will improve performance. A future version of GraphBLAS may allow this heuristic to be implemented inside GraphBLAS itself, but for now, the JIT does not second guess the user application; if it wants a new kernel, the JIT will compile it if the control is set to `GxB_JIT_ON`.

## 9.5 Mixing JIT kernels: MATLAB and Apple Silicon

In general, the JIT kernels compiled by the C interface and the kernels compiled while using GraphBLAS in MATLAB are interchangeable, and the same cache folder can be used for both. This is the default.

However, when using the `@GrB` MATLAB interface to GraphBLAS on

Apple Silicon, using an older version of MATLAB, the MATLAB JIT kernels are compiled as x86 binaries and executed inside MATLAB via Rosetta. The pure C installation may compile native Arm64 binaries for its JIT kernels. Do not mix the two. In this case, set another cache path for MATLAB using `GrB.jit` in MATLAB, or using `GrB_set` in the C interface for your native Arm64 binaries.

This issue does not apply to recent MATLAB versions on the Mac, which are native.

## 9.6 Updating the JIT when GraphBLAS source code changes

If you edit the GraphBLAS source code itself or add any files to `GraphBLAS/PreJIT`, read the instructions in `GraphBLAS/JITpackage/README.txt` for details on how to update the JIT source code.

If your cache folder (`~/.SuiteSparse/GrBx.y.z`) changes in any way except via GraphBLAS itself, simply delete your cache folder. GraphBLAS will then reconstruct the kernels there as needed.

## 9.7 Future plans for the JIT and PreJIT

### 9.7.1 Kernel fusion

The introduction of the JIT and its related PreJIT kernels allow for the future exploitation of kernel fusion via an aggressive exploitation of the GraphBLAS non-blocking mode. In that mode, multiple calls to GraphBLAS can be fused into a single kernel. There are far too many possible variants to allow a fused kernel to appear in the `GraphBLAS/Source/FactoryKernels` folder, but specific fused kernels could be created by the JIT.

### 9.7.2 Heuristics for controlling the JIT

As mentioned in Section 9.4, GraphBLAS may compile JIT kernels that are used for only tiny problems where the compile time of a single kernel will dominate any performance gains from using the compiled kernel. A heuristic could be introduced so that it compiles them only for larger problems. The possible downside of this approach is that the same JIT kernels might be needed later for larger problems.

### 9.7.3 CUDA / SYCL / OpenCL kernels

The CUDA JIT will enable NVIDIA GPUs to be exploited. There are simply too many kernels to create at compile time as the “factory kernels.” This CUDA JIT is in progress. A related JIT for SYCL / OpenCL kernels is under consideration.

### 9.7.4 Better performance for multithreaded user programs:

This version is thread-safe when used in a multithread user application, but a better JIT critical section (many readers, one writer) might be needed. The current critical section may be sufficiently fast since the typical case of work done inside the critical section is a single hash table lookup. However, the performance issues related to this have not been tested. This has no effect if all parallelism is exploited only within GraphBLAS. It only affects the case when multiple user threads each call GraphBLAS in parallel (using the `GxB_Context`; see Section 8).

## 10 GraphBLAS Options (GrB\_get and GrB\_set)

GraphBLAS includes two methods, `GrB_get` and `GrB_set` that allow the user to query GraphBLAS objects and change their state. These two methods are polymorphic wrappers for a suite of methods for each object.

The general polymorphic signatures of these methods are given below:

```
GrB_Info GrB_get (object, value, int field) ;
GrB_Info GrB_set (object, value, int field) ;
GrB_Info GrB_set (object, void *value, int field, size_t s) ;
```

where `object` can be any GraphBLAS object. The `value` can be a `GrB_Scalar`, an `int32_t` (or a pointer to `int32_t` for `GrB_get`), a string (`char *`), or a `void *` pointer. In the latter case, `GrB_set` requires an additional parameter (`size_t s`) that specifies the size of the object pointed to by `void *value`.

The non-polymorphic names have the following format, where `[OBJ]` is any GraphBLAS object.

```
GrB_Info GrB_[OBJ]_get_[KIND] (object, value, int field) ;
GrB_Info GrB_[OBJ]_set_[KIND] (object, value, int field) ;
GrB_Info GrB_[OBJ]_set_VOID (object, void *value, int field, size_t s) ;
```

The `[KIND]` suffix defines the type of second parameter, and can be: `Scalar` (for `GrB_Scalar`), `String` (for `char *`), `INT32` (for `int32_t`), and `SIZE` (for `size_t` \* for `GrB_get` only), and `VOID` (for `void *`).

The tables below list all the valid fields that can be used for each object. Each table contains four columns: (1) the `int`, (2) a column labelled R/W, (3) a column defining the C type, and a description. For the R/W column:

- If the R/W column of a table is R, then the value can be read by `GrB_get` but not written by `GrB_set`.
- R/W means that both `GrB_get` and `GrB_set` can be used any number of times, with different values.
- R/W1 means that `GrB_get` can be done multiple times, but `GrB_set` can be used only once. Subsequent calls to `GrB_set` return the error code `GrB_ALREADY_SET`.
- W means that only `GrB_set` can be used (any number of times), but `GrB_get` cannot be done.

The second parameter (`value`) of `GrB_get` and `GrB_set` can take on several different C types, and it can also be a `GrB_Scalar` that holds a value with the given C type (or that can be typecasted to the given C type):

- `int32_t`: For `GrB_set` the value parameter is `int32_t`. For `GrB_get` the value parameter is `int32_t *`. The following example sets the global number of threads, and then retrieves that value into `nthreads`.

```
GrB_set (GrB_GLOBAL, 8, GxB_NTHREADS) ;
int32_t nthreads ;
GrB_get (GrB_GLOBAL, &nthreads, GxB_NTHREADS) ;
printf ("nthreads: %d\n", nthreads) ;
```

A `GrB_Scalar` can also be used for an `int32_t` value. For `GrB_set`, the scalar must not be empty. Here is the same example but using a `GrB_Scalar` instead:

```
GrB_Scalar s ;
GrB_Scalar_new (s, GrB_INT32) ;
GrB_Scalar_setElement (s, 8) ;
GrB_set (GrB_GLOBAL, s, GxB_NTHREADS) ;
GrB_get (GrB_GLOBAL, s, GxB_NTHREADS) ;
int32_t nthreads ;
GrB_Scalar_extractElement (&nthreads, s) ;
printf ("nthreads: %d\n", nthreads) ;
```

- `char *`: The value parameter is `char *` for both `GrB_get` and `GrB_set`. A `GrB_Scalar` cannot be used. The size of the string required for `GrB_get` is given by using a `size_t *` parameter with the same field. For example:

```
size_t len ;
GrB_get (GrB_GLOBAL, &len, GrB_NAME) ;
char *name = malloc (len) ;
GrB_get (GrB_GLOBAL, name, GrB_NAME) ;
printf ("The library is: %s\n", name) ;
free (name) ;
```

To get the current JIT C compiler and then set it to something else:

```

size_t len ;
GrB_get (GrB_GLOBAL, &len, GxB_JIT_C_COMPILER_NAME) ;
char *compiler = malloc (len) ;
GrB_get (GrB_GLOBAL, compiler, GxB_JIT_C_COMPILER_NAME) ;
printf ("The current JIT compiler is: %s\n", compiler) ;
GrB_set (GrB_GLOBAL, "gcc", GxB_JIT_C_COMPILER_NAME) ;
GrB_get (GrB_GLOBAL, &len, GxB_JIT_C_COMPILER_NAME) ;
char *new_compiler = malloc (len) ;
GrB_get (GrB_GLOBAL, new_compiler, GxB_JIT_C_COMPILER_NAME) ;
printf ("The new JIT compiler is: %s\n", new_compiler) ;
free (compiler) ;
free (new_compiler) ;

```

- Other scalar data types (typically double): Only a `GrB_Scalar` can be used. When using `GrB_set` with a `GrB_Scalar`, the scalar cannot be empty. For example, to get then set the global `GxB_HYPER_SWITCH` parameter to 0.3:

```

GrB_Scalar s ;
GrB_Scalar_new (s, GrB_FP64) ;
GrB_get (GrB_GLOBAL, s, GxB_HYPER_SWITCH) ;
double hs ;
GrB_Scalar_extractElement (&hs, s) ;
printf ("current hyper_switch: %g\n", hs) ;
GrB_Scalar_setElement (s, 0.3) ;
GrB_set (GrB_GLOBAL, s, GxB_HYPER_SWITCH) ;

```

- `void *`: This type is used for all other cases. For `GrB_get`, the array must have the right size, just like a `char *` string. Use the same field first, but with `size_t *value` as the second parameter to obtain the size of the `void *` array, then use `GrB_get` with a `void *` array of the right size. In some cases, the size is always the same. For example, to query the operator of a monoid:

```

GrB_BinaryOp op ;
GrB_get (GrB_PLUS_MONOID_FP64, (void *) &op, GxB_MONOID_OPERATOR) ;
assert (op == GrB_PLUS_FP64) ;

```

For `GrB_set`, a fourth parameter is required to tell GraphBLAS the size of the input array.

## 10.1 Enum types for get/set

The get/set methods share a `int` (enum) type to specify which component of the object is to be set or retrieved.

```
typedef enum
{
    // GrB_Descriptor only:
    GrB_OUTP_FIELD = 0,      // descriptor for output of a method
    GrB_MASK_FIELD = 1,      // descriptor for the mask input of a method
    GrB_INP0_FIELD = 2,      // descriptor for the first input of a method
    GrB_INP1_FIELD = 3,      // descriptor for the second input of a method

    // all objects, including GrB_GLOBAL:
    GrB_NAME = 10,           // name of the object, as a string

    // GrB_GLOBAL only:
    GrB_LIBRARY_VER_MAJOR = 11,    // SuiteSparse:GraphBLAS version
    GrB_LIBRARY_VER_MINOR = 12,
    GrB_LIBRARY_VER_PATCH = 13,
    GrB_API_VER_MAJOR = 14,        // C API version
    GrB_API_VER_MINOR = 15,
    GrB_API_VER_PATCH = 16,
    GrB_BLOCKING_MODE = 17,       // GrB_Mode

    // GrB_GLOBAL, GrB_Matrix, GrB_Vector, GrB_Scalar (and void * serialize?):
    GrB_STORAGE_ORIENTATION_HINT = 100, // GrB_Orientation

    // GrB_Matrix, GrB_Vector, GrB_Scalar (and void * serialize):
    GrB_EL_TYPE_CODE = 102,        // a GrB_Type_code (see below)
    GrB_EL_TYPE_STRING = 106,      // name of the type

    // GrB_*Op, GrB_Monoid, and GrB_Semiring:
    GrB_INP1_TYPE_CODE = 103,      // GrB_Type_code
    GrB_INP2_TYPE_CODE = 104,
    GrB_OUTP_TYPE_CODE = 105,
    GrB_INP1_TYPE_STRING = 107,    // name of the type, as a string
    GrB_INP2_TYPE_STRING = 108,
    GrB_OUTP_TYPE_STRING = 109,

    // GrB_Type (readable only):
    GrB_SIZE = 110,               // size of the type

## 10.2 Global Options (GrB\_Global)

A single object `GrB_GLOBAL` whose type is `GrB_Global` is used to denote global settings to read or modify. To use it with `GrB_get` and `GrB_set`, pass in `GrB_GLOBAL` as the first parameter.

```

GrB_Info GrB_get (GrB_Global g, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Global g, char *      value, int f) ;
GrB_Info GrB_get (GrB_Global g, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Global g, size_t *    value, int f) ;
GrB_Info GrB_get (GrB_Global g, void *      value, int f) ;

GrB_Info GrB_set (GrB_Global g, GrB_Scalar value, int f) ;
GrB_Info GrB_set (GrB_Global g, char *      value, int f) ;
GrB_Info GrB_set (GrB_Global g, int32_t     value, int f) ;
GrB_Info GrB_set (GrB_Global g, void *      value, int f, size_t s) ;

```

int field	R/W	C type	description
GrB_LIBRARY_VER_MAJOR	R	int32_t	major version of the library

GxB_REALLOC_FUNCTION	R	void *	realloc function
GxB_FREE_FUNCTION	R	void *	free function

### 10.2.1 Global diagnostic settings

GrB\_set (GrB\_GLOBAL, ..., GxB\_BURBLE) controls the burble setting. It can also be controlled via GrB.burble(b) in the MATLAB/Octave interface.

```
GrB_set (GrB_GLOBAL, true,  GxB_BURBLE) ; // enable burble
GrB_set (GrB_GLOBAL, false, GxB_BURBLE) ; // disable burble
```

If enabled, SuiteSparse:GraphBLAS reports which internal kernels it uses, and how much time is spent. If you see the word **generic**, it means that SuiteSparse:GraphBLAS was unable to use its JIT kernels, or its faster kernels in **Source/FactoryKernels**, but used a generic kernel that relies on function pointers. This is done for user-defined types and operators when they cannot be used in the JIT, and when typecasting is performed. Generic kernels are typically slower than the JIT kernels or kernels in **Source/FactoryKernels**.

If you see a lot of `wait` statements, it may mean that a lot of time is spent finishing a matrix or vector. This may be the result of an inefficient use of the `setElement` and `assign` methods. If this occurs you might try changing the sparsity format of a vector or matrix to `GxB_BITMAP`, assuming there's enough space for it.

The following setting allows the user application to change the function used to print diagnostic output:

```
GrB_set (GrB_GLOBAL, (void *) printf, GxB_PRINTF, sizeof (void *)) ;
```

This also controls the output of the `GxB_*print` functions. By default this parameter is `NULL`, in which case the C11 `printf` function is used. The parameter is a function pointer with the same signature as the C11 `printf` function. The MATLAB/Octave interface to GraphBLAS sets it to `mexPrintf` so that GraphBLAS can print to the MATLAB/Octave Command Window.

After each call to the `printf` function, an optional `flush` function is called, which is `NULL` by default. If `NULL`, the function is not used. This can be changed with:

```
GrB_set (GrB_GLOBAL, (void *) flush, GxB_FLUSH, sizeof (void *)) ;
```

The `flush` function takes no arguments, and returns an `int` which is 0 if successful, or any nonzero value on failure (the same output as the C11 `fflush` function, except that `flush` has no inputs).

### 10.2.2 OpenMP parallelism

SuiteSparse:GraphBLAS is a parallel library, based on OpenMP. By default, all GraphBLAS operations will use up to the maximum number of threads specified by the `omp_get_max_threads` OpenMP function. For small problems, GraphBLAS may choose to use fewer threads, using two parameters: the maximum number of threads to use (which may differ from the `omp_get_max_threads` value), and a parameter called the `chunk`. Suppose `work` is a measure of the work an operation needs to perform (say the number of entries in the two input matrices for `GrB_eWiseAdd`). No more than `floor(work/chunk)` threads will be used (or one thread if the ratio is less than 1).

`GxB_NTHREADS` controls how many threads a method uses. By default (if set to zero, or `GrB_DEFAULT`), all available threads are used. The maximum

available threads is controlled by the global setting, which is `omp_get_max_threads ( )` by default. If set to some positive integer `nthreads` less than this maximum, at most `nthreads` threads will be used.

`GxB_CHUNK` is a `double` value that controls how many threads a method uses for small problems. The default `chunk` value is 65,536, but this may change in future versions, or it may be modified when GraphBLAS is installed on a particular machine.

Both parameters can be set in two ways:

- Globally: If the following methods are used, then all subsequent GraphBLAS operations will use these settings. Note the typecast, `(double)` `chunk`. This is necessary if a literal constant such as 20000 is passed as this argument. The type of the constant must be `double`.

```
int32_t nthreads_max = 40 ;
GrB_set (GrB_GLOBAL, nthreads_max, GxB_NTHREADS) ;
GrB_Scalar_new (&s, GrB_FP64) ;
GrB_Scalar_setElement (s, (double) 20000) ;
GrB_set (GrB_GLOBAL, s, GxB_CHUNK) ;
```

- Context: this object can be used to choose a different number of threads used in calls to GraphBLAS from different user threads, exploiting nested parallelism. Refer to Section 8. If a thread has engaged a context object, it ignores the global settings for `GxB_NTHREADS` and `GxB_CHUNK`, and uses the settings in its own context instead.

The smaller of `nthreads_max` and `floor(work/chunk)` is used for any given GraphBLAS operation, except that a single thread is used if this value is zero or less.

If either parameter is set to `GrB_DEFAULT`, then default values are used. The default for `nthreads_max` is the return value from `omp_get_max_threads`, and the default chunk size is currently 65,536.

If a descriptor value for either parameter is left at its default, or set to `GrB_DEFAULT`, then the global setting is used. This global setting may have been modified from its default, and this modified value will be used.

For example, suppose `omp_get_max_threads` reports 8 threads. If `GrB_set (GrB_GLOBAL, 4, GxB_NTHREADS)` is used, then the global setting is four threads, not eight.

GraphBLAS may be compiled without OpenMP, by setting `-DNOOPENMP=1`. The library will be thread-safe, with one exception. `GrB_wait` is intended to provide thread-safety by flushing the cache of one user thread so the object can be safely read by another thread. This is accomplished with `pragma omp flush`, but if OpenMP is not available, this does nothing. If OpenMP is not available or `-DNOOPENMP=1` is used, then user applications need to ensure their own thread safety when one user thread computes a result that is then read by another thread.

You can query GraphBLAS at run-time to ask if it was compiled with OpenMP:

```
bool have_openmp ;
GrB_get (GrB_GLOBAL, &have_openmp, GxB_LIBRARY_OPENMP) ;
if (!have_openmp) printf ("GraphBLAS not compiled with OpenMP\n") ;
```

Compiling GraphBLAS without OpenMP is not recommended for installation in a package manager (Linux, conda-forge, spack, brew, vcpkg, etc).

### 10.2.3 Other global options

`GrB_BLOCKING_MODE` can only be queried by `GrB_get`; it cannot be modified by `GrB_set`. The mode is the value passed to `GrB_init` (blocking or non-blocking).

All threads in the same user application share the same global options, including hypersparsity, bitmap options, and CSR/CSC format determined by `GrB_set`, and the blocking mode determined by `GrB_init`. Specific format and hypersparsity parameters of each matrix are specific to that matrix and can be independently changed.

The `GrB_LIBRARY_*` and `GxB_LIBRARY_*` options can be used to query the current implementation of SuiteSparse:GraphBLAS. The `GrB_API_*` and `GxB_API_*` options can be used to query the current GraphBLAS C API Specification.

## 10.3 GrB\_Type Options

```
GrB_Info GrB_get (GrB_Type t, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Type t, char *      value, int f) ;
GrB_Info GrB_get (GrB_Type t, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Type t, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_Type t, char *      value, int f) ;
```

int field	R/W	C type	description
GrB_EL_TYPE_CODE	R	int32_t	type code (see GrB_Type_Code)
GrB_SIZE	R	size_t	sizeof the type
GrB_NAME	R/W1	char *	name of the type. For built-in types, this returns the GraphBLAS name ("GrB_FP32" for GrB_FP32, for example). For user-defined types, the name can be any string of any length. It is not used by the JIT. It can be set at most once.
GxB_JIT_C_NAME	R/W1	char *	This must be a valid name of a C type to enable its use in the JIT. For built-in types, this returns the C name of the type ("float" for GrB_FP32, for example). The length of the name can be at most GxB_MAX_NAME_LEN, including the nul terminating byte. It can be set at most once.
GxB_JIT_C_DEFINITION	R/W1	char *	type definition, as a C typedef; built-in types return an empty string. It can be set at most once.

Built-in types cannot be modified by `GrB_set`. User-defined types can be used without setting their name or definition, but they can be used in JIT kernels only when both the JIT C name and the definition are set.

To use the JIT, all operators, monoids, and semirings that access this type must be defined after the user-defined type has been given both a name and a definition. GraphBLAS can use an operator that uses a type without a name, but it cannot use the JIT, even if the type is given a name later on after the operator is created.

The size of the type can be returned as a `size_t` C scalar, or as a `GrB_Scalar`, normally of type `GrB_UINT64`, with the examples below.

```
size_t size ;
```

```
GrB_get (GrB_FP32, &size, GrB_SIZE) ;  
assert (size == sizeof (float)) ;  
  
GrB_Scalar s ;  
GrB_Scalar_new (&s, GrB_UINT64) ;  
GrB_get (GrB_FP32, s, GrB_SIZE) ;  
GrB_Scalar_extractElement (&size, s) ;  
assert (size == sizeof (float)) ;
```

## 10.4 GrB\_UnaryOp Options

```
GrB_Info GrB_get (GrB_UnaryOp op, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_UnaryOp op, char *      value, int f) ;
GrB_Info GrB_get (GrB_UnaryOp op, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_UnaryOp op, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_UnaryOp op, char *      value, int f) ;
```

int field	R/W	C type	description
GrB_INP0_TYPE_CODE	R	int32_t	input type code (see GrB_Type_code)
GrB_OUTP_TYPE_CODE	R	int32_t	output type code
GrB_INP0_TYPE_STRING	R	char *	name of the input type
GrB_OUTP_TYPE_STRING	R	char *	name of the output type
GrB_NAME	R/W1	char *	name of the operator. For built-in operators, this returns the GraphBLAS name ("GrB_LNOT" for GrB_LNOT, for example). For user-defined operators, the name can be any string of any length. It is not used by the JIT. It can be set at most once.
GxB_JIT_C_NAME	R/W1	char *	This must be a valid name of a C function to enable its use in the JIT. The length of the name can be at most GxB_MAX_NAME_LEN, including the nul terminating byte. It can be set at most once.
GxB_JIT_C_DEFINITION	R/W1	char *	definition for a user-defined operator, as a C function; built-in operators return an empty string. It can be set at most once.

Built-in operators cannot be modified by **GrB\_set**. User-defined operators can be used without setting their name or definition, but they can be used in JIT kernels only when both the JIT C name and the definition are set.

## 10.5 GrB\_IndexUnaryOp Options

```
GrB_Info GrB_get (GrB_IndexUnaryOp op, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_IndexUnaryOp op, char *      value, int f) ;
GrB_Info GrB_get (GrB_IndexUnaryOp op, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_IndexUnaryOp op, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_IndexUnaryOp op, char *      value, int f) ;
```

int field	R/W	C type	description
GrB_INP0_TYPE_CODE	R	int32_t	1st input type code (see GrB_Type_code)
GrB_INP1_TYPE_CODE	R	int32_t	2nd input type code
GrB_OUTP_TYPE_CODE	R	int32_t	output type code
GrB_INP0_TYPE_STRING	R	char *	name of the 1st input type
GrB_INP1_TYPE_STRING	R	char *	name of the 2nd input type
GrB_OUTP_TYPE_STRING	R	char *	name of the output type
GrB_NAME	R/W1	char *	name of the operator. For built-in operators, this returns the GraphBLAS name ("GrB_TRIL" for GrB_TRIL, for example). For user-defined operators, the name can be any string of any length. It is not used by the JIT. It can be set at most once.
GxB_JIT_C_NAME	R/W1	char *	This must be a valid name of a C function to enable its use in the JIT. The length of the name can be at most GxB_MAX_NAME_LEN, including the nul terminating byte. It can be set at most once.
GxB_JIT_C_DEFINITION	R/W1	char *	definition for a user-defined operator, as a C function; built-in operators return an empty string. It can be set at most once.

Built-in operators cannot be modified by **GrB\_set**. User-defined operators can be used without setting their name or definition, but they can be used in JIT kernels only when both the JIT C name and the definition are set.

## 10.6 GrB\_BinaryOp Options

```
GrB_Info GrB_get (GrB_BinaryOp op, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_BinaryOp op, char *      value, int f) ;
GrB_Info GrB_get (GrB_BinaryOp op, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_BinaryOp op, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_BinaryOp op, char *      value, int f) ;
```

int field	R/W	C type	description
GrB_INP0_TYPE_CODE	R	int32_t	1st input type code (see GrB_Type_code)
GrB_INP1_TYPE_CODE	R	int32_t	2nd input type code
GrB_OUTP_TYPE_CODE	R	int32_t	output type code
GxB_THETA_TYPE_CODE	R	int32_t	$\Theta$ type code, if any
GrB_INP0_TYPE_STRING	R	char *	name of the 1st input type
GrB_INP1_TYPE_STRING	R	char *	name of the 2nd input type
GrB_OUTP_TYPE_STRING	R	char *	name of the output type
GxB_THETA_TYPE_STRING	R	char *	name of the $\Theta$ type, if any
GrB_NAME	R/W1	char *	name of the operator. For built-in operators, this returns the GraphBLAS name ("GrB_LOR" for GrB_LOR, for example). For user-defined operators, the name can be any string of any length. It is not used by the JIT. It can be set at most once.
GxB_JIT_C_NAME	R/W1	char *	This must be a valid name of a C function to enable its use in the JIT. The length of the name can be at most GxB_MAX_NAME_LEN, including the nul terminating byte. It can be set at most once.
GxB_JIT_C_DEFINITION	R/W1	char *	definition for a user-defined operator, as a C function; built-in operators return an empty string. It can be set at most once.
GxB_THETA	R	GrB_Scalar	value of <b>Theta</b> , if any. The type of the GrB_Scalar must match the <b>Theta</b> type of the underlying index-binary operator exactly.

Built-in operators cannot be modified by **GrB\_set**. User-defined operators can be used without setting their name or definition, but they can be used in JIT kernels only when both the JIT C name and the definition are set.

To use the JIT, all monoids and semirings that access this binary operator

must be defined after the user-defined operator has been given both a name and a definition. GraphBLAS can use a monoid or semiring that uses a binary operator without a name, but it cannot use the JIT, even if the operator is given a name later on after the operator is created.

The *\*THETA\** options can only be used in the binary operator was created by `GxB_BinaryOp_new_IndexOp`.

## 10.7 GxB\_IndexBinaryOp Options

```
GrB_Info GrB_get (GxB_IndexBinaryOp op, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GxB_IndexBinaryOp op, char *      value, int f) ;
GrB_Info GrB_get (GxB_IndexBinaryOp op, int32_t *   value, int f) ;
GrB_Info GrB_get (GxB_IndexBinaryOp op, size_t *    value, int f) ;

GrB_Info GrB_set (GxB_IndexBinaryOp op, char *      value, int f) ;
```

int field	R/W	C type	description
GrB_INP0_TYPE_CODE	R	int32_t	1st input type code (see GrB_Type_code)
GrB_INP1_TYPE_CODE	R	int32_t	2nd input type code
GrB_OUTP_TYPE_CODE	R	int32_t	output type code
GxB_THETA_TYPE_CODE	R	int32_t	$\Theta$ type code
GrB_INP0_TYPE_STRING	R	char *	name of the 1st input type
GrB_INP1_TYPE_STRING	R	char *	name of the 2nd input type
GrB_OUTP_TYPE_STRING	R	char *	name of the output type
GxB_THETA_TYPE_STRING	R	char *	name of the $\Theta$ type
GrB_NAME	R/W1	char *	name of the operator. For user-defined operators, the name can be any string of any length. It is not used by the JIT. It can be set at most once.
GxB_JIT_C_NAME	R/W1	char *	This must be a valid name of a C function to enable its use in the JIT. The length of the name can be at most GxB_MAX_NAME_LEN, including the nul terminating byte. It can be set at most once.
GxB_JIT_C_DEFINITION	R/W1	char *	definition for a user-defined operator, as a C function; built-in operators return an empty string. It can be set at most once.

There are no built-in index-binary operators, but if there are in the future, they will not be modified by `GrB_set`. User-defined operators can be used without setting their name or definition, but they can be used in JIT kernels only when both the JIT C name and the definition are set.

To use the JIT, all semirings that access this index-binary operator must be defined after the user-defined operator has been given both a name and a definition. GraphBLAS can use a semiring that uses a binary operator without a name, but it cannot use the JIT, even if the operator is given a name later on after the operator is created.

## 10.8 GrB\_Monoid Options

```
GrB_Info GrB_get (GrB_Monoid monoid, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Monoid monoid, char *      value, int f) ;
GrB_Info GrB_get (GrB_Monoid monoid, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Monoid monoid, size_t *    value, int f) ;
GrB_Info GrB_get (GrB_Monoid monoid, void *      value, int f) ;

GrB_Info GrB_set (GrB_Monoid monoid, char *      value, int f) ;
```

int field	R/W	C type	description
GrB_INP0_TYPE_CODE	R	int32_t	1st input type code (see GrB_Type_code)
GrB_INP1_TYPE_CODE	R	int32_t	2nd input type code
GrB_OUTP_TYPE_CODE	R	int32_t	output type code
GrB_INP0_TYPE_STRING	R	char *	name of the 1st input type
GrB_INP1_TYPE_STRING	R	char *	name of the 2nd input type
GrB_OUTP_TYPE_STRING	R	char *	name of the output type
GrB_NAME	R/W1	char *	name of the monoid. For built-in monoids, this returns the GraphBLAS name ("GrB_LOR_MONOID_BOOL" for GrB_LOR_MONOID_BOOL, for example). For user-defined monoids, the name can be any string of any length. It is not used by the JIT. It can be set at most once.
GxB_MONOID_IDENTITY	R	GrB_Scalar	identity value of the monoid. The type of the GrB_Scalar must match the monoid type exactly.
GxB_MONOID_TERMINAL	R	GrB_Scalar	terminal value of a terminal monoid. The type of the GrB_Scalar must match the monoid type exactly. If the monoid is not terminal, the GrB_Scalar is returned with no entry.
GxB_MONOID_OPERATOR	R	void *	binary operator of the monoid, as a GrB_BinaryOp

Built-in monoids cannot be modified by GrB\_set.

For GxB\_MONOID\_OPERATOR, the op is returned as an alias, not as a new object. For example, if a monoid is created with a user-defined binary operator, the following usage returns a shallow copy of the operator:

```

GrB_BinaryOp binop ;
GrB_BinaryOp_new (&binop, func, GrB_BOOL, GrB_BOOL, GrB_BOOL) ;
GrB_Monoid monoid ;
GrB_Monoid_new (&monoid, binop, (bool) false) ;

```

With the above objects defined, the following two code snippets do the same thing:

```

// getting an alias to the binary operator directly:
GrB_BinaryOp op ;
op = binop ;

// getting an alias to the binary operator using GrB_get:
GrB_BinaryOp op ;
GrB_get (monoid, (void *) &op, GxB_MONOID_OPERATOR) ;
assert (op == binop) ;

```

As a result, it is not valid to free both the `op` and the `binop`, since they are the same object. This usage returns the built-in `GrB_LOR` operator of the corresponding built-in monoid:

```

GrB_BinaryOp op ;
GrB_get (GrB_LOR_MONOID, (void *) &op, GxB_MONOID_OPERATOR) ;
assert (op == GrB_LOR) ;

```

## 10.9 GrB\_Semiring Options

```
GrB_Info GrB_get (GrB_Semiring semiring, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Semiring semiring, char *      value, int f) ;
GrB_Info GrB_get (GrB_Semiring semiring, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Semiring semiring, size_t *    value, int f) ;
GrB_Info GrB_get (GrB_Semiring semiring, void *      value, int f) ;

GrB_Info GrB_set (GrB_Semiring semiring, GrB_Scalar value, int f) ;
```

int field	R/W	C type	description
GrB_INP0_TYPE_CODE	R	int32_t	1st input type code (see GrB_Type_code) of the multiplicative operator
GrB_INP1_TYPE_CODE	R	int32_t	2nd input type code of the multiplicative operator
GrB_OUTP_TYPE_CODE	R	int32_t	output type code of the multiplicative operator, and the monoid type.
GxB_THETA_TYPE_CODE	R	int32_t	$\Theta$ type code, if any
GrB_INP0_TYPE_STRING	R	char *	name of the 1st input type of the multiplicative operator
GrB_INP1_TYPE_STRING	R	char *	name of the 2nd input type of the multiplicative operator
GrB_OUTP_TYPE_STRING	R	char *	name of the output type of the multiplicative operator, and the monoid type.
GxB_THETA_TYPE_STRING	R	char *	name of the $\Theta$ type, if any
GrB_NAME	R/W1	char *	name of the semiring. For built-in semirings, this returns the GraphBLAS name ("GrB_LOR_LAND_SEMIRING_BOOL" for GrB_LOR_LAND_SEMIRING_BOOL, for example). For user-defined semirings, the name can be any string of any length. It is not used by the JIT. It can be set at most once.
GxB_THETA	R	GrB_Scalar	value of Theta, if any. The type of the GrB_Scalar must match the Theta type of the underlying index-binary operator exactly.

int field	R/W	C type	description
GxB_MONOID_IDENTITY	R	GrB_Scalar	identity value of the monoid. The type of the <b>GrB_Scalar</b> must match the monoid type exactly.
GxB_MONOID_TERMINAL	R	GrB_Scalar	terminal value of a terminal monoid. The type of the <b>GrB_Scalar</b> must match the monoid type exactly. If the monoid is not terminal, the <b>GrB_Scalar</b> is returned with no entry.
GxB_MONOID_OPERATOR	R	void *	binary operator of the monoid, as a <b>GrB_BinaryOp</b> ; See Section 10.8
GxB_SEMIRING_MONOID	R	void *	monoid of the semiring, as a <b>GrB_Monoid</b>
GxB_SEMIRING_MULTIPLY	R	void *	multiplicative operator of the semiring, as a <b>GrB_BinaryOp</b>

Built-in semirings cannot be modified by **GrB\_set**.

The **GxB\_SEMIRING\_MONOID** option returns the **GrB\_Monoid** of the semiring. The **GxB\_SEMIRING\_MULTIPLY** option returns the **GrB\_BinaryOp** for the multiplicative operator of the semiring. For example:

```
// getting an alias to the monoid and multiply operator using GrB_get:
GrB_BinaryOp op ;
GrB_Monoid mon ;
GrB_Semiring semiring = GrB_PLUS_TIMES_FP32 ;
GrB_get (semiring, (void *) &mon, GxB_SEMIRING_MONOID) ;
GrB_get (semiring, (void *) &op, GxB_SEMIRING_MULTIPLY) ;
assert (op == GrB_TIMES_FP32) ;
assert (mon == GrB_PLUS_MONOID_FP32) ;
```

The binary op and monoid returned are aliases, not new objects.

The **\*THETA\*** options can only be used in the multiplicative binary operator of the semiring was created by **GxB\_BinaryOp\_new\_IndexOp**.

## 10.10 GrB\_Matrix Options

```
GrB_Info GrB_get (GrB_Matrix A, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Matrix A, char *      value, int f) ;
GrB_Info GrB_get (GrB_Matrix A, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Matrix A, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_Matrix A, GrB_Scalar value, int f) ;
GrB_Info GrB_set (GrB_Matrix A, char *      value, int f) ;
GrB_Info GrB_set (GrB_Matrix A, int32_t     value, int f) ;
```

int field	R/W	C type	description
GrB_STORAGE_ORIENTATION_HINT	R/W	int32_t	See GrB_Orientation, and Section 10.10.1.
GrB_EL_TYPE_CODE	R	int32_t	matrix type
GxB_SPARSITY_CONTROL	R/W	int32_t	See Section 10.10.4
GxB_SPARSITY_STATUS	R	int32_t	See Section 10.10.4
GxB_IS_READONLY	R	int32_t	true if it has any read-only components
GxB_WILL_WAIT	R	int32_t	will GrB_wait do anything (Section 10.10.6)
GxB_ISO	R/W	int32_t	iso status (Section 10.10.5)
GxB_ROWINDEX_INTEGER_BITS	R	int32_t	number of bits for row indices (32 or 64)
GxB_COLINDEX_INTEGER_BITS	R	int32_t	number of bits for column indices (32 or 64)
GxB_OFFSET_INTEGER_BITS	R	int32_t	number of bits for offsets (32 or 64)
GxB_ROWINDEX_INTEGER_HINT	R/W	int32_t	hint for row indices (0, 32, 64)
GxB_COLINDEX_INTEGER_HINT	R/W	int32_t	hint for column indices (0, 32, 64)
GxB_OFFSET_INTEGER_HINT	R/W	int32_t	hint for offsets (0, 32, 64)
GrB_NAME	R/W	char *	name of the matrix. This can be set any number of times.
GrB_EL_TYPE_STRING	R	char *	name of the type of the matrix.
GxB_JIT_C_NAME	R	char *	JIT C name of the type of the matrix.
GxB_HYPER_SWITCH	R/W	double	See Section 10.10.2
GxB_BITMAP_SWITCH	R/W	double	See Section 10.10.3

### 10.10.1 Storing a matrix by row or by column

The GraphBLAS `GrB_Matrix` is entirely opaque to the user application, and the GraphBLAS API does not specify how the matrix should be stored. However, choices made in how the matrix is represented in a particular implementation, such as SuiteSparse:GraphBLAS, can have a large impact on performance.

Many graph algorithms are just as fast in any format, but some algorithms are much faster in one format or the other. For example, suppose the user application stores a directed graph as a matrix  $A$ , with the edge  $(i, j)$  represented as the value  $A(i, j)$ , and the application makes many accesses to the  $i$ th row of the matrix, with `GrB_Col_extract(w, ..., A, GrB_ALL, ..., i, desc)` with the transposed descriptor (`GrB_INP0` set to `GrB_TRAN`). If the matrix is stored by column this can be extremely slow, just like the expression  $w = A(i, :)$  in MATLAB, where  $i$  is a scalar. Since this is a typical use-case in graph algorithms, the default format in SuiteSparse:GraphBLAS is to store its matrices by row, in Compressed Sparse Row format (CSR).

MATLAB stores its sparse matrices by column, in “non-hypersparse” format, in what is called the Compressed Sparse Column format, or CSC for short. An  $m$ -by- $n$  matrix in MATLAB is represented as a set of  $n$  column vectors, each with a sorted list of row indices and values of the nonzero entries in that column. As a result,  $w = A(:, j)$  is very fast in MATLAB, since the result is already held in the data structure a single list, the  $j$ th column vector. However,  $w = A(i, :)$  is very slow in MATLAB, since every column in the matrix has to be searched to see if it contains row  $i$ . In MATLAB, if many such accesses are made, it is much better to transpose the matrix (say  $AT = A'$ ) and then use  $w = AT(:, i)$  instead. This can have a dramatic impact on the performance of MATLAB.

Likewise, if  $u$  is a very sparse column vector and  $A$  is stored by column, then  $w = u' * A$  (via `GrB_vxm`) is slower than  $w = A * u$  (via `GrB_m xv`). The opposite is true if the matrix is stored by row.

SuiteSparse:GraphBLAS stores its matrices by row, by default (with one exception described below). However, it can also be instructed to store any selected matrices, or all matrices, by column instead (just like MATLAB), so that  $w = A(:, j)$  (via `GrB_Col_extract`) is very fast. The change in data format has no effect on the result, just the time and memory usage. To use a column-oriented format by default, the following can be done in a user application that tends to access its matrices by column.

```

GrB_init (...) ;
// just after GrB_init: do the following:
GrB_set (GrB_GLOBAL, GrB_COLMAJOR, GrB_STORAGE_ORIENTATION_HINT) ;

```

If this is done, and no other `GrB_set` calls are made with `GrB_STORAGE_ORIENTATION_HINT`, all matrices will be stored by column. The default format is `GrB_ROWMAJOR`.

All vectors (`GrB_Vector`) are held by column, and this cannot be changed.

By default, matrices of size `m-by-1` are held by column, regardless of the global setting described above. Matrices of size `1-by-n` with `n` not equal to 1 are held by row, regardless of the global setting. The global setting only affects matrices with both `m > 1` and `n > 1`. Empty matrices (`0-by-0`) are also controlled by the global setting.

After creating a matrix with `GrB_Matrix_new (&A, ...)`, its format can be changed arbitrarily with:

```

GrB_set (A, GrB_COLMAJOR, GrB_STORAGE_ORIENTATION_HINT) ;
GrB_set (A, GrB_ROWMAJOR, GrB_STORAGE_ORIENTATION_HINT) ;

```

If set to other values (`GrB_BOTH` or `GrB_UNKNOWN`), the format is changed to `GrB_ROWMAJOR`.

With this setting, even an `m-by-1` matrix can then be changed to be held by row, for example. Likewise, once a `1-by-n` matrix is created, it can be converted to column-oriented format.

### 10.10.2 Hypersparse matrices

MATLAB can store an `m-by-n` matrix with a very large value of `m`, since a CSC data structure takes  $O(n + |\mathbf{A}|)$  memory, independent of `m`, where  $|\mathbf{A}|$  is the number of nonzeros in the matrix. It cannot store a matrix with a huge `n`, and this structure is also inefficient when  $|\mathbf{A}|$  is much smaller than `n`. In contrast, SuiteSparse:GraphBLAS can store its matrices in *hypersparse* format, taking only  $O(|\mathbf{A}|)$  memory, independent of how it is stored (by row or by column) and independent of both `m` and `n` [BG08, BG12].

In both the CSR and CSC formats, the matrix is held as a set of sparse vectors. In non-hypersparse format, the set of sparse vectors is itself dense; all vectors are present, even if they are empty. For example, an `m-by-n` matrix in non-hypersparse CSC format contains `n` sparse vectors. Each column vector takes at least one integer to represent, even for a column with no entries. This

allows for quick lookup for a particular vector, but the memory required is  $O(n+|\mathbf{A}|)$ . With a hypersparse CSC format, the set of vectors itself is sparse, and columns with no entries take no memory at all. The drawback of the hypersparse format is that finding an arbitrary column vector  $\mathbf{j}$ , such as for the computation  $\mathbf{C}=\mathbf{A}(:,\mathbf{j})$ , takes  $O(\log k)$  time if there  $k \leq n$  vectors in the data structure. One advantage of the hypersparse structure is the memory required for an  $\mathbf{m}$ -by- $\mathbf{n}$  hypersparse CSC matrix is only  $O(|\mathbf{A}|)$ , independent of  $\mathbf{m}$  and  $\mathbf{n}$ . Algorithms that must visit all non-empty columns of a matrix are much faster when working with hypersparse matrices, since empty columns can be skipped.

The `hyper_switch` parameter controls the hypersparsity of the internal data structure for a matrix. The parameter is typically in the range 0 to 1. The default is `hyper_switch = GxB_HYPER_DEFAULT`, which is an `extern const double` value, currently set to 0.0625, or 1/16. This default ratio may change in the future.

The `hyper_switch` determines how the matrix is converted between the hypersparse and non-hypersparse formats. Let  $n$  be the number of columns of a CSC matrix, or the number of rows of a CSR matrix. The matrix can have at most  $n$  non-empty vectors.

Let  $k$  be the actual number of non-empty vectors. That is, for the CSC format,  $k \leq n$  is the number of columns that have at least one entry. Let  $h$  be the value of `hyper_switch`.

If a matrix is currently hypersparse, it can be converted to non-hypersparse if the either condition  $n \leq 1$  or  $k > 2nh$  holds, or both. Otherwise, it stays hypersparse. Note that if  $n \leq 1$  the matrix is always stored as non-hypersparse.

If currently non-hypersparse, it can be converted to hypersparse if both conditions  $n > 1$  and  $k \leq nh$  hold. Otherwise, it stays non-hypersparse. Note that if  $n \leq 1$  the matrix always remains non-hypersparse.

The default value of `hyper_switch` is assigned at startup by `GrB_init`, and can then be modified globally with `GrB_set`. All new matrices are created with the same `hyper_switch`, determined by the global value. Once a particular matrix  $\mathbf{A}$  has been constructed, its hypersparsity ratio can be modified from the default with:

```
double hyper_switch = 0.2 ;
GrB_set (A, hyper_switch, GxB_HYPER_SWITCH) ;
```

To force a matrix to always be non-hypersparse, use `hyper_switch` equal

to `GxB_NEVER_HYPER`. To force a matrix to always stay hypersparse, set `hyper_switch` to `GxB_ALWAYS_HYPER`.

A `GrB_Matrix` can thus be held in one of four formats: any combination of hyper/non-hyper and CSR/CSC. All `GrB_Vector` objects are always stored in non-hypersparse CSC format.

A new matrix created via `GrB_Matrix_new` starts with  $k = 0$  and is created in hypersparse form by default unless  $n \leq 1$  or if  $h < 0$ , where  $h$  is the global `hyper_switch` value. The matrix is created in either `GrB_ROWMAJOR` or `GrB_COLMAJOR` format, as determined by the last call to `GrB_set(GrB_GLOBAL, ..., GrB_STORAGE_ORIENTATION_HINT, ...)` or `GrB_init`.

A new matrix `C` created via `GrB_dup (&C,A)` inherits the CSR/CSC format, hypersparsity format, and `hyper_switch` from `A`.

### 10.10.3 Bitmap matrices

By default, SuiteSparse:GraphBLAS switches between all four formats (hypersparse, sparse, bitmap, and full) automatically. Let  $d = |\mathbf{A}|/mn$  for an  $m$ -by- $n$  matrix  $\mathbf{A}$  with  $|\mathbf{A}|$  entries. If the matrix is currently in sparse or hypersparse format, and is modified so that  $d$  exceeds a given threshold, it is converted into bitmap format. The default threshold is controlled by the `GxB_BITMAP_SWITCH` setting, which can be set globally, or for a particular matrix or vector.

The default value of the switch to bitmap format depends on  $\min(m, n)$ , for a matrix of size  $m$ -by- $n$ . For the global setting, the bitmap switch is a double array of size `GxB_NBITMAP_SWITCH`. The defaults are given below:

parameter	default	matrix sizes
<code>bitmap_switch [0]</code>	0.04	$\min(m, n) = 1$ (and all vectors)
<code>bitmap_switch [1]</code>	0.05	$\min(m, n) = 2$
<code>bitmap_switch [2]</code>	0.06	$\min(m, n) = 3$ to 4
<code>bitmap_switch [3]</code>	0.08	$\min(m, n) = 5$ to 8
<code>bitmap_switch [4]</code>	0.10	$\min(m, n) = 9$ to 16
<code>bitmap_switch [5]</code>	0.20	$\min(m, n) = 17$ to 32
<code>bitmap_switch [6]</code>	0.30	$\min(m, n) = 33$ to 64
<code>bitmap_switch [7]</code>	0.40	$\min(m, n) > 64$

That is, by default a `GrB_Vector` is held in bitmap format if its density exceeds 4%. To change the global settings, do the following:

```
double bswitch [GxB_NBITMAP_SWITCH] = { 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8 } ;
GrB_set (GrB_GLOBAL, (void *) bswitch, GxB_BITMAP_SWITCH,
        GxB_NBITMAP_SWITCH * sizeof (double)) ;
```

If the matrix is currently in bitmap format, it is converted to full if all entries are present, or to sparse/hypersparse if  $d$  drops below  $b/2$ , if its bitmap switch is  $b$ . A matrix or vector with  $d$  between  $b/2$  and  $b$  remains in its current format.

#### 10.10.4 Sparsity status

The sparsity status of a matrix can be queried with the following, which returns a value of GxB\_HYPERSPARSE (1), GxB\_SPARSE (2), GxB\_BITMAP (4), or GxB\_FULL (8).

```
int32_t sparsity ;
GrB_get (A, &sparsity, GxB_SPARSITY_STATUS) ;
```

The sparsity format of a matrix can be controlled with the field set to GxB\_SPARSITY\_CONTROL, for which the value can be any mix (a sum or bitwise or) of GxB\_HYPERSPARSE, GxB\_SPARSE, GxB\_BITMAP, and GxB\_FULL. By default, a matrix or vector can be held in any format, with the default setting GxB\_AUTO\_SPARSITY, which is equal to GxB\_HYPERSPARSE + GxB\_SPARSE + GxB\_BITMAP + GxB\_FULL (15). To enable a matrix to take on just GxB\_SPARSE or GxB\_FULL formats, but not GxB\_HYPERSPARSE or GxB\_BITMAP, for example, use the following:

```
GrB_set (A, GxB_SPARSE + GxB_FULL, GxB_SPARSITY_CONTROL) ;
```

In this case, SuiteSparse:GraphBLAS will hold the matrix in sparse format (CSR or CSC, depending on its GrB\_STORAGE\_ORIENTATION\_HINT), unless all entries are present, in which case it will be converted to full format.

Only the least significant 4 bits of the sparsity control are considered, so the formats can be bitwise negated. For example, to allow for any format except full:

```
GrB_set (A, ~GxB_FULL, GxB_SPARSITY_CONTROL) ;
```

#### **10.10.5 iso status**

The `GxB_ISO` option allows the iso status of a matrix or vector to be queried. The option can be set, as well. If set true, this asks GraphBLAS to attempt to revise the storage of the matrix to make it iso-valued. GraphBLAS will check all the values, and if they are all the same, the matrix is converted to an iso-valued format. If set false, the matrix is revised so that it is held in a non-iso format, if it is stored in iso-valued form.

#### **10.10.6 wait status**

The `GxB_WILL_WAIT` option can be queried with `GrB_get` to determine if a call to `GrB_wait` on the matrix, vector, or scalar will do any work.

## 10.11 GrB\_Vector Options

```
GrB_Info GrB_get (GrB_Vector v, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Vector v, char *      value, int f) ;
GrB_Info GrB_get (GrB_Vector v, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Vector v, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_Vector v, GrB_Scalar value, int f) ;
GrB_Info GrB_set (GrB_Vector v, char *      value, int f) ;
GrB_Info GrB_set (GrB_Vector v, int32_t     value, int f) ;
```

int field	R/W	C type	description
GrB_EL_TYPE_CODE	R	int32_t	vector type
GxB_SPARSITY_CONTROL	R/W	int32_t	See Section <a href="#">10.10.4</a>
GxB_SPARSITY_STATUS	R	int32_t	See Section <a href="#">10.10.4</a>
GxB_IS_READONLY	R	int32_t	true if it has any read-only components
GxB_WILL_WAIT	R	int32_t	will GrB_wait do anything (Section <a href="#">10.10.6</a> )
GxB_ISO	R/W	int32_t	iso status (Section <a href="#">10.10.5</a> )
GxB_ROWINDEX_INTEGER_BITS	R	int32_t	number of bits for row indices (32 or 64)
GxB_COLINDEX_INTEGER_BITS	R	int32_t	number of bits for column indices (32 or 64)
GxB_OFFSET_INTEGER_BITS	R	int32_t	number of bits for offsets (32 or 64)
GxB_ROWINDEX_INTEGER_HINT	R/W	int32_t	hint for row indices (0, 32, 64)
GxB_COLINDEX_INTEGER_HINT	R/W	int32_t	hint for column indices (0, 32, 64)
GxB_OFFSET_INTEGER_HINT	R/W	int32_t	hint for offsets (0, 32, 64)
GrB_NAME	R/W	char *	name of the vector.
GrB_EL_TYPE_STRING	R	char *	name of the type of the vector.
GxB_JIT_C_NAME	R	char *	JIT C name of the type of the vector.
GxB_BITMAP_SWITCH	R/W	double	See Section <a href="#">10.10.3</a>

See Section [10.10](#); a GrB\_Vector is treated as if it were an  $n$ -by-1 matrix, and is always in column major form. It is never hypersparse.

## 10.12 GrB\_Scalar Options

```
GrB_Info GrB_get (GrB_Scalar s, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Scalar s, char *      value, int f) ;
GrB_Info GrB_get (GrB_Scalar s, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Scalar s, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_Scalar s, GrB_Scalar value, int f) ;
GrB_Info GrB_set (GrB_Scalar s, char *      value, int f) ;
GrB_Info GrB_set (GrB_Scalar s, int32_t     value, int f) ;
```

int field	R/W	C type	description
GrB_EL_TYPE_CODE	R	int32_t	scalar type
GxB_SPARSITY_STATUS	R	int32_t	See Section 10.10.4
GxB_IS_READONLY	R	int32_t	true if it has any read-only components
GxB_WILL_WAIT	R	int32_t	will GrB_wait do anything (Section 10.10.6)
GxB_ISO	R/W	int32_t	iso status (Section 10.10.5)
GrB_NAME	R/W	char *	name of the scalar.
GrB_EL_TYPE_STRING	R	char *	name of the type of the scalar.
GxB_JIT_C_NAME	R	char *	JIT C name of the type of the scalar.

See Section 10.10; a GrB\_Scalar is treated as if it were a 1-by-1 matrix, and is always in column major form. It is never hypersparse.

## 10.13 Controlling the sizes of integers

Different integers are used for different parts of the matrix/vector/scalar data structure. The decision as to which integers to use is determined by the dimensions and number of entries in the matrix. The decisions can also be modified by GrB\_set and queried by GrB\_get. A matrix can have up to three different kinds of integers. If a matrix is  $m$ -by- $n$  with  $e$  entries, with default settings:

- if  $m > 2^{31}$ : 64-bit integers must be used for the row indices of a matrix; otherwise, 32-bit integers may be used.
- if  $n > 2^{31}$ : 64-bit integers must be used for the column indices of a matrix; otherwise, 32-bit integers may be used.
- if  $e > 2^{32}$ : 64-bit integers must be used for the row/column offsets of a matrix; otherwise 32-bit integers may be used.

This gives up to 8 different matrix types when the matrix is hypersparse. Sparse matrices use just two of these integer types (a sparse CSR matrix, held by row, does not store any row indices). example, if a matrix held in sparse CSR format (`GxB_SPARSE`), of size  $m$ -by- $n$  with  $e$  entries, then the value of  $m$  does not affect the integers used to store the matrix. Bitmap and full matrices use no arrays of integers at all, and are not affected by these settings. For

These decisions can be revised on a global basis and a per matrix/vector basis. Three fields can be used for `GrB_get` and `GrB_set`, for the `GrB_GLOBAL`, `GrB_Matrix`, `GrB_Vector`, and `GrB_Scalar` objects:

- `GxB_ROWINDEX_INTEGER_HINT`: for the global setting, this can be set to 32 (the default) or 64. The default (32) means that 32-bit integers are used if the number of rows of a matrix or length of a vector is not too large ( $> 2^{31}$ ), and 64-bit integers are used otherwise. On a per matrix/vector basis, setting this hint changes the integers used for row indices in the vector or matrix. The setting of zero is the default for individual matrices/vectors, which means the global setting is used.
- `GxB_COLINDEX_INTEGER_HINT`: the same as the row index hint above, except for column indices. This setting has little effect on a `GrB_Vector`, since it is held internally by GraphBLAS as an  $m$ -by-1 matrix.
- `GxB_OFFSET_INTEGER_HINT`: Internally, a sparse or hypersparse matrix or vector holds an offset array with the cumulative sum of the number of entries in each row (if held by row) or column (if held by column). A global setting of 32 is the default, so that 32-bit integers are used if the matrix has fewer than  $2^{32}$  entries. If this setting is changed to 64, then 64-bit integers are always used.

Once an object is created, the sizes of its three integers can be queried by `GrB_get` with the following fields. Each query returns the result of 32 or 64, as an integer, to denote if 32-bit or 64-bit integers are used for that component of the matrix/vector. Bitmap and full matrices always return 64.

- `GxB_ROWINDEX_INTEGER_BITS`: query the number of bits in the row index integer.
- `GxB_COLINDEX_INTEGER_BITS`: query the number of bits in the column index integer.
- `GxB_OFFSET_INTEGER_BITS`: query the number of bits in the offset integer.

## 10.14 GrB\_Descriptor Options

```
GrB_Info GrB_get (GrB_Descriptor desc, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GrB_Descriptor desc, char *      value, int f) ;
GrB_Info GrB_get (GrB_Descriptor desc, int32_t *   value, int f) ;
GrB_Info GrB_get (GrB_Descriptor desc, size_t *    value, int f) ;

GrB_Info GrB_set (GrB_Descriptor desc, GrB_Scalar value, int f) ;
GrB_Info GrB_set (GrB_Descriptor desc, char *      value, int f) ;
GrB_Info GrB_set (GrB_Descriptor desc, int32_t     value, int f) ;
```

int field	R/W	C type	description
GrB_OUTP	R/W	int32_t	GrB_DEFAULT or GrB_REPLACE
GrB_MASK	R/W	int32_t	GrB_DEFAULT, GrB_COMP, GrB_STRUCTURE, or GrB_COMP_STRUCTURE
GrB_INP0	R/W	int32_t	GrB_DEFAULT or GrB_TRAN
GrB_INP1	R/W	int32_t	GrB_DEFAULT or GrB_TRAN
GxB_AxB_METHOD	R/W	int32_t	Method used by GrB_mxm (GrB_DEFAULT, GxB_AxB_GUSTAVSON, GxB_AxB_HASH, GxB_AxB_SAXPY, or GxB_AxB_DOT).
GxB_SORT	R/W	int32_t	if true, GrB_mxm returns its output in sorted form.
GxB_COMPRESSION	R/W	int32_t	compression method for serialize methods.
GxB_ROWINDEX_LIST	R/W	int32_t	how the GrB_Vector I is interpreted.
GxB_COLINDEX_LIST	R/W	int32_t	how the GrB_Vector J is interpreted.
GxB_VALUE_LIST	R/W	int32_t	how GrB_Vector X is interpreted (for GrB_build only).
GrB_NAME	R/W	char *	name of the descriptor. This can be set any number of times for user-defined descriptors. Built-in descriptors have the same name as the variable name ("GrB_DESC_T1" for the GrB_DESC_T1 descriptor, for example)

The following table describes each option. See Section 6.16 for more details.

Descriptor field	Default	Non-default
GrB_OUTP	GrB_DEFAULT: The output matrix is not cleared. The operation computes $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$ .	GrB_REPLACE: After computing $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$ , the output $\mathbf{C}$ is cleared of all entries. Then $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{Z}$ is performed.
GrB_MASK	GrB_DEFAULT: The Mask is not complemented. $\text{Mask}(\mathbf{i}, \mathbf{j})=1$ means the value $C_{ij}$ can be modified by the operation, while $\text{Mask}(\mathbf{i}, \mathbf{j})=0$ means the value $C_{ij}$ shall not be modified by the operation.	GrB_COMP: The Mask is complemented. $\text{Mask}(\mathbf{i}, \mathbf{j})=0$ means the value $C_{ij}$ can be modified by the operation, while $\text{Mask}(\mathbf{i}, \mathbf{j})=1$ means the value $C_{ij}$ shall not be modified by the operation. GrB_STRUCTURE: The values of the Mask are ignored. If $\text{Mask}(\mathbf{i}, \mathbf{j})$ is an entry in the Mask matrix, it is treated as if $\text{Mask}(\mathbf{i}, \mathbf{j})=1$ . The two options GrB_COMP and GrB_STRUCTURE can be combined, with two subsequent calls, or with a single call with the setting GrB_COMP+GrB_STRUCTURE.
GrB_INP0	GrB_DEFAULT: The first input is not transposed prior to using it in the operation.	GrB_TRAN: The first input is transposed prior to using it in the operation. Only matrices are transposed, never vectors.
GrB_INP1	GrB_DEFAULT: The second input is not transposed prior to using it in the operation.	GrB_TRAN: The second input is transposed prior to using it in the operation. Only matrices are transposed, never vectors.
GxB_AxB_METHOD	GrB_DEFAULT: The method for $\mathbf{C}=\mathbf{A}*\mathbf{B}$ is selected automatically.	GxB_AxB_method: The selected method is used to compute $\mathbf{C}=\mathbf{A}*\mathbf{B}$ .
GxB_SORT	GrB_DEFAULT: The computation of $\mathbf{C}=\mathbf{A}*\mathbf{B}$ may leave $\mathbf{C}$ in a jumbled state; GrB_wait will finalize the matrix.	any nonzero value: $\mathbf{C}=\mathbf{A}*\mathbf{B}$ always returns $\mathbf{C}$ in final, sorted form.
GxB_COMPRESSION	GrB_DEFAULT: Serialize methods will use the default method, ZSTD (level 1)	See Section <a href="#">6.11</a>
GxB_ROWINDEX_LIST	GrB_DEFAULT or GxB_USE_VALUES: use the values of $\mathbf{I}$	GxB_USE_INDICES: use the indices of $\mathbf{I}$ ; GxB_IS_STRIDE: $\mathbf{I}$ is a strided range (lo:inc:hi)
GxB_COLINDEX_LIST	GrB_DEFAULT or GxB_USE_VALUES: use the values of $\mathbf{J}$	GxB_USE_INDICES: use the indices of $\mathbf{J}$ ; GxB_IS_STRIDE: $\mathbf{J}$ is a strided range (lo:inc:hi)
GxB_VALUE_LIST	GrB_DEFAULT or GxB_USE_VALUES: use the values of $\mathbf{X}$	GxB_USE_INDICES: use the indices

## 10.15 GxB\_Context Options

```
GrB_Info GrB_get (GxB_Context Context, GrB_Scalar value, int f) ;
GrB_Info GrB_get (GxB_Context Context, char *      value, int f) ;
GrB_Info GrB_get (GxB_Context Context, int32_t *   value, int f) ;
GrB_Info GrB_get (GxB_Context Context, size_t *    value, int f) ;

GrB_Info GrB_set (GxB_Context Context, GrB_Scalar value, int f) ;
GrB_Info GrB_set (GxB_Context Context, char *      value, int f) ;
GrB_Info GrB_set (GxB_Context Context, int32_t     value, int f) ;
```

int field	R/W	C type	description
GxB_NTHREADS	R/W	int32_t	number of OpenMP threads to use; See Section <a href="#">10.2.2</a>
GxB_CHUNK	R/W	double	chunk factor for task creation; See Section <a href="#">10.2.2</a>
GrB_NAME	R/W	char *	name of the context. This can be set any number of times for user-defined contexts. Built-in contexts have the same name as the variable name ("GxB_CONTEXT_WORLD" for the GxB_CONTEXT_WORLD context, for example)

NOTE: the non-polymorphic names for this method are `GxB_Context_get_[KIND]` and `GxB_Context_set_[KIND]`, where `KIND` can be: `Scalar` (for `GrB_Scalar`), `String` (for `char *`), `INT` (for `int32_t`), and `SIZE` (for `size_t *` for `GrB_get` only), and `VOID` (for `void *`). The non-polymorphic suffix of `INT` is used here instead of `INT32` because `GxB_Context_*_INT32` appear as historical methods in version v8.0 and earlier, which are now deprecated.

For the `int32_t` type, the use of the polymorphic `GrB_set` and `GrB_get` accesses the correct version of this method. When using non-polymorphic methods, the use of `GxB_Context_get_INT` and `GxB_Context_set_INT` is recommended.

## 10.16 Options for inspecting a serialized blob

```
GrB_Info GrB_get (const void *blob, GrB_Scalar value, int f, size_t blobsize) ;
GrB_Info GrB_get (const void *blob, char *      value, int f, size_t blobsize) ;
GrB_Info GrB_get (const void *blob, int32_t *   value, int f, size_t blobsize) ;
GrB_Info GrB_get (const void *blob, size_t *    value, int f, size_t blobsize) ;
```

int field	R/W	C type	description
GrB_STORAGE_ORIENTATION_HINT	R	int32_t	See GrB_Orientation, and Section <a href="#">10.10.1</a> .
GrB_EL_TYPE_CODE	R	int32_t	type of matrix in the blob
GxB_SPARSITY_CONTROL	R	int32_t	See Section <a href="#">10.10.4</a>
GxB_SPARSITY_STATUS	R	int32_t	See Section <a href="#">10.10.4</a>
GxB_ISO	R	int32_t	iso status (Section <a href="#">10.10.5</a> )
GxB_ROWINDEX_INTEGER_BITS	R	int32_t	number of bits for row indices (32 or 64)
GxB_COLINDEX_INTEGER_BITS	R	int32_t	number of bits for column indices (32 or 64)
GxB_OFFSET_INTEGER_BITS	R	int32_t	number of bits for offsets (32 or 64)
GxB_ROWINDEX_INTEGER_HINT	R	int32_t	hint for row indices (0, 32, 64)
GxB_COLINDEX_INTEGER_HINT	R	int32_t	hint for column indices (0, 32, 64)
GxB_OFFSET_INTEGER_HINT	R	int32_t	hint for offsets (0, 32, 64)
GrB_NAME	R	char *	name of the matrix in the blob.
GrB_EL_TYPE_STRING	R	char *	name of the type of the matrix in the blob.
GxB_JIT_C_NAME	R	char *	JIT C name of the type of the matrix in the blob.
GxB_HYPER_SWITCH	R	double	See Section <a href="#">10.10.2</a>
GxB_BITMAP_SWITCH	R	double	See Section <a href="#">10.10.3</a>

The GrB\_Matrix\_serialize and GxB\_Matrix\_serialize methods create a *blob* as a single array of bytes that contains all content of a GrB\_Matrix. These GrB\_get methods can query a blob for the same values that can be queried for a GrB\_Matrix. The blob cannot be modified by GrB\_set.

Note that these GrB\_get methods add a fourth parameter, the size of the blob. All other GrB\_get methods have just three parameters: the object, the value, and the field.

## 11 SuiteSparse:GraphBLAS Colon and Index Notation

MATLAB/Octave uses a colon notation to index into matrices, such as  $C=A(2:4,3:8)$ , which extracts  $C$  as 3-by-6 submatrix from  $A$ , from rows 2 through 4 and columns 3 to 8 of the matrix  $A$ . A single colon is used to denote all rows,  $C=A(:,9)$ , or all columns,  $C=A(12,:)$ , which refers to the 9th column and 12th row of  $A$ , respectively. An arbitrary integer list can be given as well, such as the MATLAB/Octave statements:

```
I = [2 1 4] ;
J = [3 5] ;
C = A (I,J) ;
```

which creates the 3-by-2 matrix  $C$  as follows:

$$C = \begin{bmatrix} a_{2,3} & a_{2,5} \\ a_{1,3} & a_{1,5} \\ a_{4,3} & a_{4,5} \end{bmatrix}$$

The GraphBLAS API can do the equivalent of  $C=A(I,J)$ ,  $C=A(:,J)$ ,  $C=A(I,:)$ , and  $C=A(:,:)$ , by passing a parameter `const GrB_Index *I` as either an array of size `ni`, or as the special value `GrB_ALL`, which corresponds to the stand-alone colon  $C=A(:,J)$ , and the same can be done for  $J$ . To compute  $C=A(2:4,3:8)$  in GraphBLAS requires the user application to create two explicit integer arrays  $I$  and  $J$  of size 3 and 5, respectively, and then fill them with the explicit values  $[2,3,4]$  and  $[3,4,5,6,7,8]$ . This works well if the lists are small, or if the matrix has more entries than rows or columns.

However, particularly with hypersparse matrices, the size of the explicit arrays  $I$  and  $J$  can vastly exceed the number of entries in the matrix. When using its hypersparse format, SuiteSparse:GraphBLAS allows the user application to create a `GrB_Matrix` with dimensions up to  $2^{60}$ , with no memory constraints. The only constraint on memory usage in a hypersparse matrix is the number of entries in the matrix.

For example, creating a  $n$ -by- $n$  matrix  $A$  of type `GrB_FP64` with  $n = 2^{60}$  and one million entries is trivial to do in Version 2.1 (and later) of SuiteSparse:GraphBLAS, taking at most 24MB of space. SuiteSparse:GraphBLAS

Version 2.1 (or later) could do this on an old smartphone. However, using just the pure GraphBLAS API, constructing  $C=A(0:(n/2), 0:(n/2))$  in SuiteSparse Version 2.0 would require the creation of an integer array  $I$  of size  $2^{59}$ , containing the sequence 0, 1, 2, 3, ..., requiring about 4 ExaBytes of memory (4 million terabytes). This is roughly 1000 times larger than the memory size of the world's largest computer in 2018.

SuiteSparse:GraphBLAS Version 2.1 and later extends the GraphBLAS API with a full implementation of the MATLAB colon notation for integers,  $I=\text{begin}:\text{inc}:\text{end}$ . This extension allows the construction of the matrix  $C=A(0:(n/2), 0:(n/2))$  in this example, with dimension  $2^{59}$ , probably taking just milliseconds on an old smartphone.

The `GrB_extract`, `GrB_assign`, and `GxB_subassign` operations (described in the Section 12) each have parameters that define a list of integer indices, using two parameters:

```
const GrB_Index *I ;    // an array, or a special value GrB_ALL
GrB_Index ni ;         // the size of I, or a special value
```

These two parameters define five kinds of index lists, which can be used to specify either an explicit or implicit list of row indices and/or column indices. The length of the list of indices is denoted  $|I|$ . This discussion applies equally to the row indices  $I$  and the column indices  $J$ . The five kinds are listed below.

1. An explicit list of indices, such as  $I = [2 \ 1 \ 4 \ 7 \ 2]$  in MATLAB notation, is handled by passing in  $I$  as a pointer to an array of size 5, and passing  $ni=5$  as the size of the list. The length of the explicit list is  $ni=|I|$ . Duplicates may appear, except that for some uses of `GrB_assign` and `GxB_subassign`, duplicates lead to undefined behavior according to the GraphBLAS C API Specification. SuiteSparse:GraphBLAS specifies how duplicates are handled in all cases, as an addition to the specification. See Section 12.10 for details.
2. To specify all rows of a matrix, use  $I = \text{GrB\_ALL}$ . The parameter  $ni$  is ignored. This is equivalent to  $C=A(:, J)$  in MATLAB. In GraphBLAS, this is the sequence  $0:(m-1)$  if  $A$  has  $m$  rows, with length  $|I|=m$ . If  $J$  is used the columns of an  $m$ -by- $n$  matrix, then  $J=\text{GrB\_ALL}$  refers to all columns, and is the sequence  $0:(n-1)$ , of length  $|J|=n$ .

**SPEC:** If `I` or `J` are `GrB_ALL`, the specification requires that `ni` be passed in as `m` (the number of rows) and `nj` be passed in as `n`. Any other value is an error. SuiteSparse:GraphBLAS ignores these scalar inputs and treats them as if they are equal to their only possible correct value.

3. To specify a contiguous range of indices, such as `I=10:20` in MATLAB, the array `I` has size 2, and `ni` is passed to SuiteSparse:GraphBLAS as the special value `ni = GxB_RANGE`. The beginning index is `I[GxB_BEGIN]` and the ending index is `I[GxB_END]`. Both values must be non-negative since `GrB_Index` is an unsigned integer (`uint64_t`). The value of `I[GxB_INC]` is ignored.

```
// to specify I = 10:20
GrB_Index I [2], ni = GxB_RANGE ;
I [GxB_BEGIN] = 10 ;           // the start of the sequence
I [GxB_END ] = 20 ;           // the end of the sequence
```

Let  $b = I[GxB\_BEGIN]$ , let  $e = I[GxB\_END]$ , The sequence has length zero if  $b > e$ ; otherwise the length is  $|I| = (e - b) + 1$ .

4. To specify a strided range of indices with a non-negative stride, such as `I=3:2:10`, the array `I` has size 3, and `ni` has the special value `GxB_STRIDE`. This is the sequence 3, 5, 7, 9, of length 4. Note that 10 does not appear in the list. The end point need not appear if the increment goes past it.

```
// to specify I = 3:2:10
GrB_Index I [3], ni = GxB_STRIDE ;
I [GxB_BEGIN ] = 3 ;           // the start of the sequence
I [GxB_INC   ] = 2 ;           // the increment
I [GxB_END   ] = 10 ;          // the end of the sequence
```

The `GxB_STRIDE` sequence is the same as the `List` generated by the following for loop:

```
int64_t k = 0 ;
GrB_Index *List = (a pointer to an array of large enough size)
for (int64_t i = I [GxB_BEGIN] ; i <= I [GxB_END] ; i += I [GxB_INC])
{
    // i is the kth entry in the sequence
    List [k++] = i ;
}
```

Then passing the explicit array `List` and its length `ni=k` has the same effect as passing in the array `I` of size 3, with `ni=GxB_STRIDE`. The latter is simply much faster to produce, and much more efficient for SuiteSparse:GraphBLAS to process.

Let  $b = I[\text{GxB\_BEGIN}]$ , let  $e = I[\text{GxB\_END}]$ , and let  $\Delta = I[\text{GxB\_INC}]$ . The sequence has length zero if  $b > e$  or  $\Delta = 0$ . Otherwise, the length of the sequence is

$$|I| = \left\lfloor \frac{e - b}{\Delta} \right\rfloor + 1$$

5. In MATLAB notation, if the stride is negative, the sequence is decreasing. For example, `10:-2:1` is the sequence 10, 8, 6, 4, 2, in that order. In SuiteSparse:GraphBLAS, use `ni = GxB_BACKWARDS`, with an array `I` of size 3. The following example specifies defines the equivalent of the MATLAB expression `10:-2:1` in SuiteSparse:GraphBLAS:

```
// to specify I = 10:-2:1
GrB_Index I [3], ni = GxB_BACKWARDS ;
I [GxB_BEGIN ] = 10 ;      // the start of the sequence
I [GxB_INC    ] = 2 ;      // the magnitude of the increment
I [GxB_END    ] = 1 ;      // the end of the sequence
```

The value -2 cannot be assigned to the `GrB_Index` array `I`, since that is an unsigned type. The signed increment is represented instead with the special value `ni = GxB_BACKWARDS`. The `GxB_BACKWARDS` sequence is the same as generated by the following for loop:

```
int64_t k = 0 ;
GrB_Index *List = (a pointer to an array of large enough size)
for (int64_t i = I [GxB_BEGIN] ; i >= I [GxB_END] ; i -= I [GxB_INC])
{
    // i is the kth entry in the sequence
    List [k++] = i ;
}
```

Let  $b = I[\text{GxB\_BEGIN}]$ , let  $e = I[\text{GxB\_END}]$ , and let  $\Delta = I[\text{GxB\_INC}]$  (note that  $\Delta$  is not negative). The sequence has length zero if  $b < e$  or  $\Delta = 0$ . Otherwise, the length of the sequence is

$$|I| = \left\lfloor \frac{b - e}{\Delta} \right\rfloor + 1$$

Since `GrB_Index` is an unsigned integer, all three values `I[GxB_BEGIN]`, `I[GxB_INC]`, and `I[GxB_END]` must be non-negative.

Just as in MATLAB, it is valid to specify an empty sequence of length zero. For example, `I = 5:3` has length zero in MATLAB and the same is true for a `GxB_RANGE` sequence in SuiteSparse:GraphBLAS, with `I[GxB_BEGIN]=5` and `I[GxB_END]=3`. This has the same effect as array `I` with `ni=0`.

## 12 GraphBLAS Operations

The next sections define each of the GraphBLAS operations, also listed in the table below.

GrB_mxm	matrix-matrix multiply	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}\mathbf{B}$
GrB_vxm	vector-matrix multiply	$\mathbf{w}^T\langle\mathbf{m}^T\rangle = \mathbf{w}^T \odot \mathbf{u}^T \mathbf{A}$
GrB_mxv	matrix-vector multiply	$\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{A}\mathbf{u}$
GrB_eWiseMult	element-wise, set intersection	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot (\mathbf{A} \otimes \mathbf{B})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot (\mathbf{u} \otimes \mathbf{v})$
GrB_eWiseAdd	element-wise, set union	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot (\mathbf{A} \oplus \mathbf{B})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot (\mathbf{u} \oplus \mathbf{v})$
GxB_eWiseUnion	element-wise, set union	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot (\mathbf{A} \oplus \mathbf{B})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot (\mathbf{u} \oplus \mathbf{v})$
GrB_extract	extract submatrix	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}(\mathbf{I}, \mathbf{J})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{u}(\mathbf{i})$
GrB_assign	assign submatrix with submask for $\mathbf{C}$	$\mathbf{C}\langle\mathbf{M}\rangle(\mathbf{I}, \mathbf{J}) = \mathbf{C}(\mathbf{I}, \mathbf{J}) \odot \mathbf{A}$ $\mathbf{w}\langle\mathbf{m}\rangle(\mathbf{i}) = \mathbf{w}(\mathbf{i}) \odot \mathbf{u}$
GxB_subassign	assign submatrix, with submask for $\mathbf{C}(\mathbf{I}, \mathbf{J})$	$\mathbf{C}(\mathbf{I}, \mathbf{J})\langle\mathbf{M}\rangle = \mathbf{C}(\mathbf{I}, \mathbf{J}) \odot \mathbf{A}$ $\mathbf{w}(\mathbf{i})\langle\mathbf{m}\rangle = \mathbf{w}(\mathbf{i}) \odot \mathbf{u}$
GrB_apply	apply unary operator	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(\mathbf{A})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(\mathbf{u})$
	apply binary operator	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(x, \mathbf{A})$ $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(\mathbf{A}, y)$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(x, \mathbf{x})$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(\mathbf{u}, y)$
		$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot f(\mathbf{A}, i, j, k)$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot f(\mathbf{u}, i, 0, k)$
	apply index-unary op	
GrB_select	select entries	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \text{select}(\mathbf{A}, i, j, k)$ $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \text{select}(\mathbf{u}, i, 0, k)$
GrB_reduce	reduce to vector	$\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot [\oplus_j \mathbf{A}(:, j)]$
	reduce to scalar	$s = s \odot [\oplus_{ij} \mathbf{A}(I, J)]$
GrB_transpose	transpose	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}^T$
GrB_kronecker	Kronecker product	$\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \text{kron}(\mathbf{A}, \mathbf{B})$

If an error occurs, `GrB_error(&err,C)` or `GrB_error(&err,w)` returns details about the error, for operations that return a modified matrix  $\mathbf{C}$  or vector  $\mathbf{w}$ . The only operation that cannot return an error string is reduction to a  $\mathbf{C}$  scalar with `GrB_reduce`.

## 12.1 GrB\_mxm: matrix-matrix multiply

```

GrB_Info GrB_mxm                                // C<Mask> = accum (C, A*B)
(
    GrB_Matrix C,                                // input/output matrix for results
    const GrB_Matrix Mask,                       // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,                    // optional accum for Z=accum(C,T)
    const GrB_Semiring semiring,                 // defines '+' and '*' for A*B
    const GrB_Matrix A,                          // first input:  matrix A
    const GrB_Matrix B,                          // second input: matrix B
    const GrB_Descriptor desc                     // descriptor for C, Mask, A, and B
) ;

```

GrB\_mxm multiplies two sparse matrices A and B using the `semiring`. The input matrices A and B may be transposed according to the descriptor, `desc` (which may be NULL) and then typecasted to match the multiply operator of the `semiring`. Next,  $T=A*B$  is computed on the `semiring`, precisely defined in the `GB_spec_mxm.m` script in `GraphBLAS/Test`. The actual algorithm exploits sparsity and does not take  $O(n^3)$  time, but it computes the following:

```

[m s] = size (A.matrix) ;
[s n] = size (B.matrix) ;
T.matrix = zeros (m, n, multiply.ztype) ;
T.pattern = zeros (m, n, 'logical') ;
T.matrix (:,:) = identity ;                % the identity of the semiring's monoid
T.class = multiply.ztype ;                 % the ztype of the semiring's multiply op
A = cast (A.matrix, multiply.xtype) ;      % the xtype of the semiring's multiply op
B = cast (B.matrix, multiply.ytype) ;      % the ytype of the semiring's multiply op
for j = 1:n
    for i = 1:m
        for k = 1:s
            % T (i,j) += A (i,k) * B (k,j), using the semiring
            if (A.pattern (i,k) && B.pattern (k,j))
                z = multiply (A (i,k), B (k,j)) ;
                T.matrix (i,j) = add (T.matrix (i,j), z) ;
                T.pattern (i,j) = true ;
            end
        end
    end
end
end
end

```

Finally, T is typecasted into the type of C, and the results are written back into C via the `accum` and `Mask`,  $C\langle M \rangle = C \odot T$ . The latter step is reflected in the MATLAB function `GB_spec_accum_mask.m`, discussed in Section 2.3.

**Performance considerations:** Suppose all matrices are in `GrB_COLMAJOR` format, and  $B$  is extremely sparse but  $A$  is not as sparse. Then computing  $C=A*B$  is very fast, and much faster than when  $A$  is extremely sparse. For example, if  $A$  is square and  $B$  is a column vector that is all nonzero except for one entry  $B(j,0)=1$ , then  $C=A*B$  is the same as extracting column  $A(:,j)$ . This is very fast if  $A$  is stored by column but slow if  $A$  is stored by row. If  $A$  is a sparse row with a single entry  $A(0,i)=1$ , then  $C=A*B$  is the same as extracting row  $B(i,:)$ . This is fast if  $B$  is stored by row but slow if  $B$  is stored by column.

If the user application needs to repeatedly extract rows and columns from a matrix, whether by matrix multiplication or by `GrB_extract`, then keep two copies: one stored by row, and other by column, and use the copy that results in the fastest computation.

By default, `GrB_mxm`, `GrB_mxv`, `GrB_vxm`, and `GrB_reduce` (to vector) can return their result in a jumbled state, with the sort left pending. It can sometimes be faster for these methods to do the sort as they compute their result. Use the `GxB_SORT` descriptor setting to select this option. Refer to Section 6.16 for details.

## 12.2 GrB\_vxm: vector-matrix multiply

```

GrB_Info GrB_vxm                                // w'<mask> = accum (w, u'*A)
(
    GrB_Vector w,                                // input/output vector for results
    const GrB_Vector mask,                       // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,                   // optional accum for z=accum(w,t)
    const GrB_Semiring semiring,                // defines '+' and '*' for u'*A
    const GrB_Vector u,                         // first input: vector u
    const GrB_Matrix A,                        // second input: matrix A
    const GrB_Descriptor desc                   // descriptor for w, mask, and A
) ;

```

`GrB_vxm` multiplies a row vector  $u'$  times a matrix  $A$ . The matrix  $A$  may be first transposed according to `desc` (as the second input, `GrB_INP1`); the column vector  $u$  is never transposed via the descriptor. The inputs  $u$  and  $A$  are typecasted to match the `xtype` and `ytype` inputs, respectively, of the multiply operator of the `semiring`. Next, an intermediate column vector  $t = A' * u$  is computed on the `semiring` using the same method as `GrB_mxm`. Finally, the column vector  $t$  is typecasted from the `ztype` of the multiply operator of the `semiring` into the type of  $w$ , and the results are written back into  $w$  using the optional accumulator `accum` and `mask`.

The last step is  $w\langle m \rangle = w \odot t$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices.

**Performance considerations:** If the `GrB_STORAGE_ORIENTATION_HINT` of  $A$  is `GrB_ROWMAJOR`, and the default descriptor is used ( $A$  is not transposed), then `GrB_vxm` is faster than `GrB_mxv` with its default descriptor, when the vector  $u$  is very sparse. However, if the `GrB_STORAGE_ORIENTATION_HINT` of  $A$  is `GrB_COLMAJOR`, then `GrB_mxv` with its default descriptor is faster than `GrB_vxm` with its default descriptor, when the vector  $u$  is very sparse. Using the non-default `GrB_TRAN` descriptor for  $A$  makes the `GrB_vxm` operation equivalent to `GrB_mxv` with its default descriptor (with the operands reversed in the multiplier, as well). The reverse is true as well; `GrB_mxv` with `GrB_TRAN` is the same as `GrB_vxm` with a default descriptor.

## 12.3 GrB\_m xv: matrix-vector multiply

```

GrB_Info GrB_m xv                                     // w<mask> = accum (w, A*u)
(
    GrB_Vector w,                                     // input/output vector for results
    const GrB_Vector mask,                           // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,                         // optional accum for z=accum(w,t)
    const GrB_Semiring semiring,                     // defines '+' and '*' for A*B
    const GrB_Matrix A,                              // first input: matrix A
    const GrB_Vector u,                              // second input: vector u
    const GrB_Descriptor desc                         // descriptor for w, mask, and A
) ;

```

`GrB_m xv` multiplies a matrix `A` times a column vector `u`. The matrix `A` may be first transposed according to `desc` (as the first input); the column vector `u` is never transposed via the descriptor. The inputs `A` and `u` are typecasted to match the `xtype` and `ytype` inputs, respectively, of the multiply operator of the `semiring`. Next, an intermediate column vector `t=A*u` is computed on the `semiring` using the same method as `GrB_m xm`. Finally, the column vector `t` is typecasted from the `ztype` of the multiply operator of the `semiring` into the type of `w`, and the results are written back into `w` using the optional accumulator `accum` and `mask`.

The last step is  $\mathbf{w}\langle \mathbf{m} \rangle = \mathbf{w} \odot \mathbf{t}$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices.

**Performance considerations:** Refer to the discussion of `GrB_v xm`. In SuiteSparse:GraphBLAS, `GrB_m xv` is very efficient when `u` is sparse or dense, when the default descriptor is used, and when the matrix is `GrB_COLMAJOR`. When `u` is very sparse and `GrB_INP0` is set to its non-default `GrB_TRAN`, then this method is not efficient if the matrix is in `GrB_COLMAJOR` format. If an application needs to perform  $\mathbf{A}' * \mathbf{u}$  repeatedly where `u` is very sparse, then use the `GrB_ROWMAJOR` format for `A` instead.

## 12.4 GrB\_eWiseMult: element-wise operations, set intersection

Element-wise “multiplication” is shorthand for applying a binary operator element-wise on two matrices or vectors **A** and **B**, for all entries that appear in the set intersection of the patterns of **A** and **B**. This is like **A.\*B** for two sparse matrices in MATLAB, except that in GraphBLAS any binary operator can be used, not just multiplication.

The pattern of the result of the element-wise “multiplication” is exactly this set intersection. Entries in **A** but not **B**, or visa versa, do not appear in the result.

Let  $\otimes$  denote the binary operator to be used. The computation  $\mathbf{T} = \mathbf{A} \otimes \mathbf{B}$  is given below. Entries not in the intersection of **A** and **B** do not appear in the pattern of **T**. That is:

$$\begin{aligned} &\text{for all entries } (i, j) \text{ in } \mathbf{A} \cap \mathbf{B} \\ &\quad t_{ij} = a_{ij} \otimes b_{ij} \end{aligned}$$

Depending on what kind of operator is used and what the implicit value is assumed to be, this can give the Hadamard product. This is the case for **A.\*B** in MATLAB since the implicit value is zero. However, computing a Hadamard product is not necessarily the goal of the **eWiseMult** operation. It simply applies any binary operator, built-in or user-defined, to the set intersection of **A** and **B**, and discards any entry outside this intersection. Its usefulness in a user’s application does not depend upon it computing a Hadamard product in all cases. The operator need not be associative, commutative, nor have any particular property except for type compatibility with **A** and **B**, and the output matrix **C**.

The generic name for this operation is **GrB\_eWiseMult**, which can be used for both matrices and vectors.

### 12.4.1 GrB\_Vector\_eWiseMult: element-wise vector multiply

```

GrB_Info GrB_eWiseMult          // w<mask> = accum (w, u.*v)
(
    GrB_Vector w,                // input/output vector for results
    const GrB_Vector mask,       // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(w,t)
    const <operator> multiply,    // defines '.*' for t=u.*v
    const GrB_Vector u,          // first input: vector u
    const GrB_Vector v,          // second input: vector v
    const GrB_Descriptor desc    // descriptor for w and mask
) ;

```

`GrB_Vector_eWiseMult` computes the element-wise “multiplication” of two vectors  $\mathbf{u}$  and  $\mathbf{v}$ , element-wise using any binary operator (not just times). The vectors are not transposed via the descriptor. The vectors  $\mathbf{u}$  and  $\mathbf{v}$  are first typecasted into the first and second inputs of the `multiply` operator. Next, a column vector  $\mathbf{t}$  is computed, denoted  $\mathbf{t} = \mathbf{u} \otimes \mathbf{v}$ . The pattern of  $\mathbf{t}$  is the set intersection of  $\mathbf{u}$  and  $\mathbf{v}$ . The result  $\mathbf{t}$  has the type of the output `ztype` of the `multiply` operator.

The `operator` is typically a `GrB_BinaryOp`, but the method is type-generic for this parameter. If given a monoid (`GrB_Monoid`), the additive operator of the monoid is used as the `multiply` binary operator. If given a semiring (`GrB_Semiring`), the multiply operator of the semiring is used as the `multiply` binary operator. The `multiply` operator may be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

The next and final step is  $\mathbf{w}(\mathbf{m}) = \mathbf{w} \odot \mathbf{t}$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices. Note for all GraphBLAS operations, including this one, the accumulator  $\mathbf{w} \odot \mathbf{t}$  is always applied in a set union manner, even though  $\mathbf{t} = \mathbf{u} \otimes \mathbf{v}$  for this operation is applied in a set intersection manner.

### 12.4.2 GrB\_Matrix\_eWiseMult: element-wise matrix multiply

```

GrB_Info GrB_eWiseMult          // C<Mask> = accum (C, A.*B)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(C,T)
    const <operator> multiply,    // defines '.*' for T=A.*B
    const GrB_Matrix A,          // first input:  matrix A
    const GrB_Matrix B,          // second input: matrix B
    const GrB_Descriptor desc     // descriptor for C, Mask, A, and B
) ;

```

`GrB_Matrix_eWiseMult` computes the element-wise “multiplication” of two matrices **A** and **B**, element-wise using any binary operator (not just times). The input matrices may be transposed first, according to the descriptor `desc`. They are then typecasted into the first and second inputs of the `multiply` operator. Next, a matrix **T** is computed, denoted  $\mathbf{T} = \mathbf{A} \otimes \mathbf{B}$ . The pattern of **T** is the set intersection of **A** and **B**. The result **T** has the type of the output `ztype` of the `multiply` operator.

The `multiply` operator is typically a `GrB_BinaryOp`, but the method is type-generic for this parameter. If given a monoid (`GrB_Monoid`), the additive operator of the monoid is used as the `multiply` binary operator. If given a semiring (`GrB_Semiring`), the multiply operator of the semiring is used as the `multiply` binary operator. The `multiply` operator may be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

The operation can be expressed in MATLAB notation as:

```

[nrows, ncols] = size (A.matrix) ;
T.matrix = zeros (nrows, ncols, multiply.ztype) ;
T.class = multiply.ztype ;
p = A.pattern & B.pattern ;
A = cast (A.matrix (p), multiply.xtype) ;
B = cast (B.matrix (p), multiply.ytype) ;
T.matrix (p) = multiply (A, B) ;
T.pattern = p ;

```

The final step is  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$ , as described in Section 2.3. Note for all GraphBLAS operations, including this one, the accumulator  $\mathbf{C} \odot \mathbf{T}$  is always applied in a set union manner, even though  $\mathbf{T} = \mathbf{A} \otimes \mathbf{B}$  for this operation is applied in a set intersection manner.

## 12.5 GrB\_eWiseAdd: element-wise operations, set union

Element-wise “addition” is shorthand for applying a binary operator element-wise on two matrices or vectors  $\mathbf{A}$  and  $\mathbf{B}$ , for all entries that appear in the set intersection of the patterns of  $\mathbf{A}$  and  $\mathbf{B}$ . This is like  $\mathbf{A}+\mathbf{B}$  for two sparse matrices in MATLAB, except that in GraphBLAS any binary operator can be used, not just addition. The pattern of the result of the element-wise “addition” is the set union of the pattern of  $\mathbf{A}$  and  $\mathbf{B}$ . Entries in neither in  $\mathbf{A}$  nor in  $\mathbf{B}$  do not appear in the result.

Let  $\oplus$  denote the binary operator to be used. The computation  $\mathbf{T} = \mathbf{A} \oplus \mathbf{B}$  is exactly the same as the computation with accumulator operator as described in Section 2.3. It acts like a sparse matrix addition, except that any operator can be used. The pattern of  $\mathbf{A} \oplus \mathbf{B}$  is the set union of the patterns of  $\mathbf{A}$  and  $\mathbf{B}$ , and the operator is applied only on the set intersection of  $\mathbf{A}$  and  $\mathbf{B}$ . Entries not in either the pattern of  $\mathbf{A}$  or  $\mathbf{B}$  do not appear in the pattern of  $\mathbf{T}$ . That is:

$$\begin{aligned} &\text{for all entries } (i, j) \text{ in } \mathbf{A} \cap \mathbf{B} \\ &\quad t_{ij} = a_{ij} \oplus b_{ij} \\ &\text{for all entries } (i, j) \text{ in } \mathbf{A} \setminus \mathbf{B} \\ &\quad t_{ij} = a_{ij} \\ &\text{for all entries } (i, j) \text{ in } \mathbf{B} \setminus \mathbf{A} \\ &\quad t_{ij} = b_{ij} \end{aligned}$$

The only difference between element-wise “multiplication” ( $\mathbf{T} = \mathbf{A} \otimes \mathbf{B}$ ) and “addition” ( $\mathbf{T} = \mathbf{A} \oplus \mathbf{B}$ ) is the pattern of the result, and what happens to entries outside the intersection. With  $\otimes$  the pattern of  $\mathbf{T}$  is the intersection; with  $\oplus$  it is the set union. Entries outside the set intersection are dropped for  $\otimes$ , and kept for  $\oplus$ ; in both cases the operator is only applied to those (and only those) entries in the intersection. Any binary operator can be used interchangeably for either operation.

Element-wise operations do not operate on the implicit values, even implicitly, since the operations make no assumption about the semiring. As a result, the results can be different from MATLAB, which can always assume the implicit value is zero. For example,  $\mathbf{C}=\mathbf{A}-\mathbf{B}$  is the conventional matrix subtraction in MATLAB. Computing  $\mathbf{A}-\mathbf{B}$  in GraphBLAS with `eWiseAdd` will apply the `MINUS` operator to the intersection, entries in  $\mathbf{A}$  but not  $\mathbf{B}$  will be unchanged and appear in  $\mathbf{C}$ , and entries in neither  $\mathbf{A}$  nor  $\mathbf{B}$  do not appear in  $\mathbf{C}$ . For these cases, the results matches the MATLAB  $\mathbf{C}=\mathbf{A}-\mathbf{B}$ . Entries in  $\mathbf{B}$  but not  $\mathbf{A}$  do appear in  $\mathbf{C}$  but they are not negated; they cannot be subtracted

from an implicit value in **A**. This is by design. If conventional matrix subtraction of two sparse matrices is required, and the implicit value is known to be zero, use **GrB\_apply** to negate the values in **B**, and then use **eWiseAdd** with the **PLUS** operator, to compute  $\mathbf{A} + (-\mathbf{B})$ .

The generic name for this operation is **GrB\_eWiseAdd**, which can be used for both matrices and vectors.

There is another minor difference in two variants of the element-wise functions. If given a **semiring**, the **eWiseAdd** functions use the binary operator of the semiring’s monoid, while the **eWiseMult** functions use the multiplicative operator of the semiring.

### 12.5.1 GrB\_Vector\_eWiseAdd: element-wise vector addition

```
GrB_Info GrB_eWiseAdd          // w<mask> = accum (w, u+v)
(
    GrB_Vector w,              // input/output vector for results
    const GrB_Vector mask,     // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,  // optional accum for z=accum(w,t)
    const <operator> add,      // defines '+' for t=u+v
    const GrB_Vector u,        // first input:  vector u
    const GrB_Vector v,        // second input: vector v
    const GrB_Descriptor desc   // descriptor for w and mask
) ;
```

**GrB\_Vector\_eWiseAdd** computes the element-wise “addition” of two vectors **u** and **v**, element-wise using any binary operator (not just plus). The vectors are not transposed via the descriptor. Entries in the intersection of **u** and **v** are first typecasted into the first and second inputs of the **add** operator. Next, a column vector **t** is computed, denoted  $\mathbf{t} = \mathbf{u} \oplus \mathbf{v}$ . The pattern of **t** is the set union of **u** and **v**. The result **t** has the type of the output **ztype** of the **add** operator.

The **add** operator is typically a **GrB\_BinaryOp**, but the method is type-generic for this parameter. If given a monoid (**GrB\_Monoid**), the additive operator of the monoid is used as the **add** binary operator. If given a semiring (**GrB\_Semiring**), the additive operator of the monoid of the semiring is used as the **add** binary operator. The **add** operator may be a binary operator created by **GxB\_BinaryOp\_new\_IndexOp**.

The final step is  $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{t}$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices.

### 12.5.2 GrB\_Matrix\_eWiseAdd: element-wise matrix addition

```

GrB_Info GrB_eWiseAdd          // C<Mask> = accum (C, A+B)
(
    GrB_Matrix C,              // input/output matrix for results
    const GrB_Matrix Mask,     // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,  // optional accum for Z=accum(C,T)
    const <operator> add,       // defines '+' for T=A+B
    const GrB_Matrix A,        // first input:  matrix A
    const GrB_Matrix B,        // second input: matrix B
    const GrB_Descriptor desc   // descriptor for C, Mask, A, and B
) ;

```

`GrB_Matrix_eWiseAdd` computes the element-wise “addition” of two matrices  $A$  and  $B$ , element-wise using any binary operator (not just plus). The input matrices may be transposed first, according to the descriptor `desc`. Entries in the intersection then typecasted into the first and second inputs of the `add` operator. Next, a matrix  $T$  is computed, denoted  $\mathbf{T} = \mathbf{A} \oplus \mathbf{B}$ . The pattern of  $T$  is the set union of  $A$  and  $B$ . The result  $T$  has the type of the output `ztype` of the `add` operator.

The `add` operator is typically a `GrB_BinaryOp`, but the method is type-generic for this parameter. If given a monoid (`GrB_Monoid`), the additive operator of the monoid is used as the `add` binary operator. If given a semiring (`GrB_Semiring`), the additive operator of the monoid of the semiring is used as the `add` binary operator. The `add` operator may be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

The operation can be expressed in MATLAB notation as:

```

[nrows, ncols] = size (A.matrix) ;
T.matrix = zeros (nrows, ncols, add.ztype) ;
p = A.pattern & B.pattern ;
A = GB_mex_cast (A.matrix (p), add.xtype) ;
B = GB_mex_cast (B.matrix (p), add.ytype) ;
T.matrix (p) = add (A, B) ;
p = A.pattern & ~B.pattern ; T.matrix (p) = cast (A.matrix (p), add.ztype) ;
p = ~A.pattern & B.pattern ; T.matrix (p) = cast (B.matrix (p), add.ztype) ;
T.pattern = A.pattern | B.pattern ;
T.class = add.ztype ;

```

Except for when typecasting is performed, this is identical to how the `accum` operator is applied in Figure 1.

The final step is  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$ , as described in Section 2.3.

## 12.6 GxB\_eWiseUnion: element-wise operations, set union

`GxB_eWiseUnion` computes a result with the same pattern `GrB_eWiseAdd`, namely, a set union of its two inputs. It differs in how the binary operator is applied.

Let  $\oplus$  denote the binary operator to be used. The operator is applied to every entry in **A** and **B**. A pair of scalars,  $\alpha$  and  $\beta$  (`alpha` and `beta` in the API, respectively) define the inputs to the operator when entries are present in one matrix but not the other.

```

for all entries  $(i, j)$  in  $\mathbf{A} \cap \mathbf{B}$ 
     $t_{ij} = a_{ij} \oplus b_{ij}$ 
for all entries  $(i, j)$  in  $\mathbf{A} \setminus \mathbf{B}$ 
     $t_{ij} = a_{ij} \oplus \beta$ 
for all entries  $(i, j)$  in  $\mathbf{B} \setminus \mathbf{A}$ 
     $t_{ij} = \alpha \oplus b_{ij}$ 

```

`GxB_eWiseUnion` is useful in contexts where `GrB_eWiseAdd` cannot be used because of the typecasting rules of GraphBLAS. In particular, suppose **A** and **B** are matrices with a user-defined type, and suppose `<` is a user-defined operator that compares two entries of this type and returns a Boolean value. Then  $\mathbf{C} = \mathbf{A} < \mathbf{B}$  can be computed with `GxB_eWiseUnion` but not with `GrB_eWiseAdd`. In the latter, if  $\mathbf{A}(i, j)$  is present but  $\mathbf{B}(i, j)$  is not, then  $\mathbf{A}(i, j)$  must typecasted to the type of **C** (`GrB_BOOL` in this case), and the assignment  $\mathbf{C}(i, j) = (\text{bool}) \mathbf{A}(i, j)$  would be performed. This is not possible because user-defined types cannot be typecasted to any other type.

Another advantage of `GxB_eWiseUnion` is its performance. For example, the MATLAB/Octave expression  $\mathbf{C} = \mathbf{A} - \mathbf{B}$  computes  $\mathbf{C}(i, j) = -\mathbf{B}(i, j)$  when  $\mathbf{A}(i, j)$  is not present. This cannot be done with a single call `GrB_eWiseAdd`, but it can be done with a single call to `GxB_eWiseUnion`, with the `GrB_MINUS_FP64` operator, and with both `alpha` and `beta` scalars equal to zero. It is possible to compute this result with a temporary matrix,  $\mathbf{E} = -\mathbf{B}$ , computed with `GrB_apply` and `GrB_AINV_FP64`, followed by a call to `GrB_eWiseAdd` to compute  $\mathbf{C} = \mathbf{A} + \mathbf{E}$ , but this is slower than a single call to `GxB_eWiseUnion`, and uses more memory.

### 12.6.1 GxB\_Vector\_eWiseUnion: element-wise vector addition

```
GrB_Info GxB_eWiseUnion          // w<mask> = accum (w, u+v)
(
    GrB_Vector w,                // input/output vector for results
    const GrB_Vector mask,       // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(w,t)
    const GrB_BinaryOp add,      // defines '+' for t=u+v
    const GrB_Vector u,          // first input: vector u
    const GrB_Scalar alpha,      //
    const GrB_Vector v,         // second input: vector v
    const GrB_Scalar beta,       //
    const GrB_Descriptor desc    // descriptor for w and mask
) ;
```

Identical to `GrB_Vector_eWiseAdd` except that two scalars are used to define how to compute the result when entries are present in one of the two input vectors (`u` and `v`), but not the other. Each of the two input scalars, `alpha` and `beta` must contain an entry. When computing the result `t=u+v`, if `u(i)` is present but `v(i)` is not, then `t(i)=u(i)+beta`. Likewise, if `v(i)` is present but `u(i)` is not, then `t(i)=alpha+v(i)`, where `+` denotes the binary operator, `add`. The `add` operator may be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

### 12.6.2 GxB\_Matrix\_eWiseUnion: element-wise matrix addition

```
GrB_Info GxB_eWiseUnion          // C<M> = accum (C, A+B)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(C,T)
    const GrB_BinaryOp add,      // defines '+' for T=A+B
    const GrB_Matrix A,          // first input:  matrix A
    const GrB_Scalar alpha,      //
    const GrB_Matrix B,          // second input: matrix B
    const GrB_Scalar beta,       //
    const GrB_Descriptor desc    // descriptor for C, M, A, and B
) ;
```

Identical to `GrB_Matrix_eWiseAdd` except that two scalars are used to define how to compute the result when entries are present in one of the two input matrices (A and B), but not the other. Each of the two input scalars, `alpha` and `beta` must contain an entry. When computing the result  $T=A+B$ , if  $A(i,j)$  is present but  $B(i,j)$  is not, then  $T(i,j)=A(i,j)+\text{beta}$ . Likewise, if  $B(i,j)$  is present but  $A(i,j)$  is not, then  $T(i,j)=\text{alpha}+B(i,j)$ , where  $+$  denotes the binary operator, `add`. The `add` operator may be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

## 12.7 GrB\_extract: submatrix extraction

The `GrB_extract` function is a generic name for three specific functions: `GrB_Vector_extract`, `GrB_Col_extract`, and `GrB_Matrix_extract`. The generic name appears in the function signature, but the specific function name is used when describing what each variation does.

### 12.7.1 GrB\_Vector\_extract: extract subvector from vector

```
GrB_Info GrB_extract          // w<mask> = accum (w, u(I))
(
    GrB_Vector w,              // input/output vector for results
    const GrB_Vector mask,     // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,  // optional accum for z=accum(w,t)
    const GrB_Vector u,        // first input: vector u
    const GrB_Index *I,        // row indices
    const GrB_Index ni,        // number of row indices
    const GrB_Descriptor desc   // descriptor for w and mask
) ;
```

`GrB_Vector_extract` extracts a subvector from another vector, identical to  $\mathbf{t} = \mathbf{u}(\mathbf{I})$  in MATLAB where  $\mathbf{I}$  is an integer vector of row indices. Refer to `GrB_Matrix_extract` for further details; vector extraction is the same as matrix extraction with  $n$ -by-1 matrices. See Section 11 for a description of  $\mathbf{I}$  and  $ni$ . The final step is  $\mathbf{w}(\mathbf{m}) = \mathbf{w} \odot \mathbf{t}$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices.

### 12.7.2 GxB\_Vector\_extract\_Vector: extract subvector from vector

```
GrB_Info GrB_extract          // w<mask> = accum (w, u(I))
(
    GrB_Vector w,              // input/output vector for results
    const GrB_Vector mask,     // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,  // optional accum for z=accum(w,t)
    const GrB_Vector u,        // first input: vector u
    const GrB_Vector I_vector, // row indices
    const GrB_Descriptor desc   // descriptor for w and mask
) ;
```

`GxB_Vector_extract_Vector` is identical to `GrB_Vector_extract`, except that the row indices are given by the `GrB_Vector`  $\mathbf{I}$  with  $ni$  entries. The interpretation of  $\mathbf{I\_vector}$  is controlled by descriptor setting `GxB_ROWINDEX_LIST`.

The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.7.3 GrB\_Matrix\_extract: extract submatrix from matrix

```
GrB_Info GrB_extract          // C<Mask> = accum (C, A(I,J))
(
    GrB_Matrix C,              // input/output matrix for results
    const GrB_Matrix Mask,     // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,  // optional accum for Z=accum(C,T)
    const GrB_Matrix A,        // first input:  matrix A
    const GrB_Index *I,         // row indices
    const GrB_Index ni,        // number of row indices
    const GrB_Index *J,        // column indices
    const GrB_Index nj,        // number of column indices
    const GrB_Descriptor desc   // descriptor for C, Mask, and A
) ;
```

`GrB_Matrix_extract` extracts a submatrix from another matrix, identical to  $T = A(I, J)$  in MATLAB where  $I$  and  $J$  are integer vectors of row and column indices, respectively, except that indices are zero-based in GraphBLAS and one-based in MATLAB. The input matrix  $A$  may be transposed first, via the descriptor. The type of  $T$  and  $A$  are the same. The size of  $C$  is  $|I|$ -by- $|J|$ . Entries outside  $A(I, J)$  are not accessed and do not take part in the computation. More precisely, assuming the matrix  $A$  is not transposed, the matrix  $T$  is defined as follows:

```
T.matrix = zeros (ni, nj) ;    % a matrix of size ni-by-nj
T.pattern = false (ni, nj) ;
for i = 1:ni
    for j = 1:nj
        if (A (I(i),J(j)).pattern)
            T (i,j).matrix = A (I(i),J(j)).matrix ;
            T (i,j).pattern = true ;
        end
    end
end
```

If duplicate indices are present in  $I$  or  $J$ , the above method defines the result in  $T$ . Duplicates result in the same values of  $A$  being copied into different places in  $T$ . See Section 11 for a description of the row indices  $I$  and  $ni$ , and the column indices  $J$  and  $nj$ . The final step is  $C\langle M \rangle = C \odot T$ , as described in Section 2.3.

**Performance considerations:** If A is not transposed via input descriptor: if |I| is small, then it is fastest if A is GrB\_ROWMAJOR; if |J| is small, then it is fastest if A is GrB\_COLMAJOR. The opposite is true if A is transposed.

#### 12.7.4 GxB\_Matrix\_extract\_Vector: extract submatrix from matrix

```
GrB_Info GrB_extract          // C<Mask> = accum (C, A(I,J))
(
    GrB_Matrix C,              // input/output matrix for results
    const GrB_Matrix Mask,     // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,  // optional accum for Z=accum(C,T)
    const GrB_Matrix A,        // first input:  matrix A
    const GrB_Vector I_vector, // row indices
    const GrB_Vector J_vector, // column indices
    const GrB_Descriptor desc   // descriptor for C, M, and A
);
```

GxB\_Matrix\_extract\_Vector is identical to GrB\_Matrix\_extract, except that the row indices are given by the GrB\_Vector I with ni entries, and the column indices are given by the GrB\_Vector J with nj entries. The interpretation of I\_vector and J\_vector are controlled by descriptor setting GxB\_ROWINDEX\_LIST and GxB\_COLINDEX\_LIST, respectively. The method can use either the indices or values of each of the input vectors, or it can use the values as a stride (lo:inc:hi); the default is to use the values. See Section 6.16.4 for details.

#### 12.7.5 GrB\_Col\_extract: extract column vector from matrix

```
GrB_Info GrB_extract          // w<mask> = accum (w, A(I,j))
(
    GrB_Vector w,              // input/output matrix for results
    const GrB_Vector mask,     // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,  // optional accum for z=accum(w,t)
    const GrB_Matrix A,        // first input:  matrix A
    const GrB_Index *I,        // row indices
    const GrB_Index ni,        // number of row indices
    const GrB_Index j,         // column index
    const GrB_Descriptor desc   // descriptor for w, mask, and A
);
```

GrB\_Col\_extract extracts a subvector from a matrix, identical to  $t = A(I, j)$  in MATLAB where I is an integer vector of row indices and where j is a single

column index. The input matrix **A** may be transposed first, via the descriptor, which results in the extraction of a single row **j** from the matrix **A**, the result of which is a column vector **w**. The type of **t** and **A** are the same. The size of **w** is **|I|**-by-1.

See Section 11 for a description of the row indices **I** and **ni**. The final step is  $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{t}$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices.

**Performance considerations:** If **A** is not transposed: it is fastest if the format of **A** is **GrB\_COLMAJOR**. The opposite is true if **A** is transposed.

#### 12.7.6 GxB\_Col\_extract\_Vector: extract column vector from matrix

```
GrB_Info GrB_extract           // w<mask> = accum (w, A(I,j))
(
    GrB_Vector w,               // input/output matrix for results
    const GrB_Vector mask,      // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(w,t)
    const GrB_Matrix A,         // first input:  matrix A
    const GrB_Vector I_vector,   // row indices
    const GrB_Index j,          // column index
    const GrB_Descriptor desc    // descriptor for w, mask, and A
) ;
```

**GxB\_Col\_extract\_Vector** is identical to **GrB\_Col\_extract**, except that the row indices are given by the **GrB\_Vector** **I** with **ni** entries. The interpretation of **I\_vector** is controlled by descriptor setting **GxB\_ROWINDEX\_LIST**. The method can use either the indices or values of the input vector, or it can use the values as a stride (**lo:inc:hi**); the default is to use the values. See Section 6.16.4 for details.

## 12.8 GrB\_assign: submatrix assignment

The methods described in this section are all variations of the form  $C(I, J) = A$ , which modifies a submatrix of the matrix  $C$ . All methods can be used in their generic form with the single name `GrB_assign`. These methods are very similar to their `GxB_subassign` counterparts in Section 12.9. They differ primarily in the size of the `Mask`, and how the `GrB_REPLACE` option works. Section 12.11 compares `GxB_subassign` and `GrB_assign`.

See Section 11 for a description of  $I$ ,  $ni$ ,  $J$ , and  $nj$ .

### 12.8.1 GrB\_Vector\_assign: assign to a subvector

```
GrB_Info GrB_assign          // w<mask>(I) = accum (w(I),u)
(
    GrB_Vector w,             // input/output vector for results
    const GrB_Vector mask,    // optional mask for w, unused if NULL
    const GrB_BinaryOp accum, // optional accum for z=accum(w(I),t)
    const GrB_Vector u,       // first input: vector u
    const GrB_Index *I,       // row indices
    const GrB_Index ni,       // number of row indices
    const GrB_Descriptor desc  // descriptor for w and mask
);
```

`GrB_Vector_assign` operates on a subvector  $w(I)$  of  $w$ , modifying it with the vector  $u$ . The `mask` vector has the same size as  $w$ . The method is identical to `GrB_Matrix_assign` described in Section 12.8.3, where all matrices have a single column each. The only other difference is that the input  $u$  in this method is not transposed via the `GrB_INPO` descriptor.

### 12.8.2 GxB\_Vector\_assign\_Vector: assign to a subvector

```
GrB_Info GrB_assign          // w<mask>(I) = accum (w(I),u)
(
    GrB_Vector w,             // input/output vector for results
    const GrB_Vector mask,    // optional mask for w, unused if NULL
    const GrB_BinaryOp accum, // optional accum for z=accum(w(I),t)
    const GrB_Vector u,       // first input: vector u
    const GrB_Vector I_vector, // row indices
    const GrB_Descriptor desc  // descriptor for w and mask
);
```

`GxB_Vector_assign_Vector` is identical to `GrB_Vector_assign`, except that the row indices are given by the `GrB_Vector I` with `ni` entries. The interpretation of `I_vector` is controlled by descriptor setting `GxB_ROWINDEX_LIST`. The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.8.3 GrB\_Matrix\_assign: assign to a submatrix

```
GrB_Info GrB_assign          // C<Mask>(I,J) = accum (C(I,J),A)
(
    GrB_Matrix C,             // input/output matrix for results
    const GrB_Matrix Mask,    // optional mask for C, unused if NULL
    const GrB_BinaryOp accum, // optional accum for Z=accum(C(I,J),T)
    const GrB_Matrix A,       // first input:  matrix A
    const GrB_Index *I,       // row indices
    const GrB_Index ni,       // number of row indices
    const GrB_Index *J,       // column indices
    const GrB_Index nj,       // number of column indices
    const GrB_Descriptor desc  // descriptor for C, Mask, and A
);
```

`GrB_Matrix_assign` operates on a submatrix  $S$  of  $C$ , modifying it with the matrix  $A$ . It may also modify all of  $C$ , depending on the input descriptor `desc` and the `Mask`.

Step	GraphBLAS notation	description
1	$S = C(I, J)$	extract $C(I, J)$ submatrix
2	$S = S \odot A$	apply the accumulator (but not the mask) to $S$
3	$Z = C$	make a copy of $C$
4	$Z(I, J) = S$	put the submatrix into $Z(I, J)$
5	$C\langle M \rangle = Z$	apply the mask/replace phase to all of $C$

In contrast to `GxB_subassign`, the `Mask` has the same as  $C$ .

Step 1 extracts the submatrix and then Step 2 applies the accumulator (or  $S = A$  if `accum` is `NULL`). The `Mask` is not yet applied.

Step 3 makes a copy of the  $C$  matrix, and then Step 4 writes the submatrix  $S$  into  $Z$ . This is the same as Step 3 of `GxB_subassign`, except that it operates on a temporary matrix  $Z$ .

Finally, Step 5 writes  $Z$  back into  $C$  via the `Mask`, using the `Mask/Replace`

Phase described in Section 2.3. If `GrB_REPLACE` is enabled, then all of  $\mathbf{C}$  is cleared prior to writing  $\mathbf{Z}$  via the mask. As a result, the `GrB_REPLACE` option can delete entries outside the  $\mathbf{C}(\mathbf{I}, \mathbf{J})$  submatrix.

**Performance considerations:** If  $\mathbf{A}$  is not transposed: if  $|\mathbf{I}|$  is small, then it is fastest if the format of  $\mathbf{C}$  is `GrB_ROWMAJOR`; if  $|\mathbf{J}|$  is small, then it is fastest if the format of  $\mathbf{C}$  is `GrB_COLMAJOR`. The opposite is true if  $\mathbf{A}$  is transposed.

#### 12.8.4 `GxB_Matrix_assign_Vector`: assign to a submatrix

```
GrB_Info GrB_assign          // C<Mask>(I,J) = accum (C(I,J),A)
(
    GrB_Matrix C,            // input/output matrix for results
    const GrB_Matrix Mask,   // optional mask for C, unused if NULL
    const GrB_BinaryOp accum, // optional accum for Z=accum(C(I,J),T)
    const GrB_Matrix A,      // first input:  matrix A
    const GrB_Vector I_vector, // row indices
    const GrB_Vector J_vector, // column indices
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_assign_Vector` is identical to `GrB_Matrix_assign`, except that the row indices are given by the `GrB_Vector`  $\mathbf{I}$  with  $n_i$  entries, and the column indices are given by the `GrB_Vector`  $\mathbf{J}$  with  $n_j$  entries. The interpretation of  $\mathbf{I\_vector}$  and  $\mathbf{J\_vector}$  are controlled by descriptor setting `GxB_ROWINDEX_LIST` and `GxB_COLINDEX_LIST`, respectively. The method can use either the indices or values of each of the input vectors, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.8.5 GrB\_Col\_assign: assign to a sub-column of a matrix

```
GrB_Info GrB_assign          // C<mask>(I,j) = accum (C(I,j),u)
(
    GrB_Matrix C,             // input/output matrix for results
    const GrB_Vector mask,     // optional mask for C(:,j), unused if NULL
    const GrB_BinaryOp accum,  // optional accum for z=accum(C(I,j),t)
    const GrB_Vector u,        // input vector
    const GrB_Index *I,        // row indices
    const GrB_Index ni,        // number of row indices
    const GrB_Index j,         // column index
    const GrB_Descriptor desc   // descriptor for C(:,j) and mask
) ;
```

GrB\_Col\_assign modifies a single sub-column of a matrix C. It is the same as GrB\_Matrix\_assign where the index vector J[0]=j is a single column index, and where all matrices in GrB\_Matrix\_assign (except C) consist of a single column.

Unlike GrB\_Matrix\_assign, the mask is a vector with the same size as a single column of C.

The input descriptor GrB\_INP0 is ignored; the input vector u is not transposed. Refer to GrB\_Matrix\_assign for further details.

**Performance considerations:** GrB\_Col\_assign is much faster than GrB\_Row\_assign if the format of C is GrB\_COLMAJOR. GrB\_Row\_assign is much faster than GrB\_Col\_assign if the format of C is GrB\_ROWMAJOR.

### 12.8.6 GxB\_Col\_assign\_Vector: assign to a sub-column of a matrix

```
GrB_Info GrB_assign          // C<mask>(I,j) = accum (C(I,j),u)
(
    GrB_Matrix C,             // input/output matrix for results
    const GrB_Vector mask,     // optional mask for C(:,j), unused if NULL
    const GrB_BinaryOp accum,  // optional accum for z=accum(C(I,j),t)
    const GrB_Vector u,        // input vector
    const GrB_Vector I_vector, // row indices
    GrB_Index j,               // column index
    const GrB_Descriptor desc
) ;
```

GxB\_Col\_assign\_Vector is identical to GrB\_Col\_assign, except that the row indices are given by the GrB\_Vector I with ni entries. The interpretation of I\_vector is controlled by descriptor setting GxB\_ROWINDEX\_LIST.

The method can use either the indices or values of the input vector, or it can use the values as a stride (lo:inc:hi); the default is to use the values. See Section 6.16.4 for details.

### 12.8.7 GrB\_Row\_assign: assign to a sub-row of a matrix

```
GrB_Info GrB_assign          // C[mask']>(i,J) = accum (C(i,J),u')
(
    GrB_Matrix C,            // input/output matrix for results
    const GrB_Vector mask,   // optional mask for C(i,:), unused if NULL
    const GrB_BinaryOp accum, // optional accum for z=accum(C(i,J),t)
    const GrB_Vector u,      // input vector
    const GrB_Index i,       // row index
    const GrB_Index *J,      // column indices
    const GrB_Index nj,      // number of column indices
    const GrB_Descriptor desc // descriptor for C(i,:) and mask
);
```

`GrB_Row_assign` modifies a single sub-row of a matrix `C`. It is the same as `GrB_Matrix_assign` where the index vector `I[0]=i` is a single row index, and where all matrices in `GrB_Matrix_assign` (except `C`) consist of a single row.

Unlike `GrB_Matrix_assign`, the `mask` is a vector with the same size as a single row of `C`.

The input descriptor `GrB_INP0` is ignored; the input vector `u` is not transposed. Refer to `GrB_Matrix_assign` for further details.

**Performance considerations:** `GrB_Col_assign` is much faster than `GrB_Row_assign` if the format of `C` is `GrB_COLMAJOR`. `GrB_Row_assign` is much faster than `GrB_Col_assign` if the format of `C` is `GrB_ROWMAJOR`.

### 12.8.8 GxB\_Row\_assign\_Vector: assign to a sub-row of a matrix

```
GrB_Info GrB_assign          // C<mask'>(i,J) = accum (C(i,J),u')
(
    GrB_Matrix C,             // input/output matrix for results
    const GrB_Vector mask,    // mask for C(i,:), unused if NULL
    const GrB_BinaryOp accum, // optional accum for z=accum(C(i,J),t)
    const GrB_Vector u,       // input vector
    GrB_Index i,              // row index
    const GrB_Vector J_vector, // column indices
    const GrB_Descriptor desc
) ;
```

`GxB_Row_assign_Vector` is identical to `GrB_Row_assign`, except that the column indices are given by the `GrB_Vector` `J` with `nj` entries. The interpretation of `J_vector` is controlled by descriptor setting `GxB_COLINDEX_LIST`. The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.8.9 GrB\_Vector\_assign\_<type>: assign a scalar to a subvector

```
GrB_Info GrB_assign          // w<mask>(I) = accum (w(I),x)
(
    GrB_Vector w,             // input/output vector for results
    const GrB_Vector mask,    // optional mask for w, unused if NULL
    const GrB_BinaryOp accum, // optional accum for z=accum(w(I),x)
    const <type> x,           // scalar to assign to w(I)
    const GrB_Index *I,       // row indices
    const GrB_Index ni,       // number of row indices
    const GrB_Descriptor desc // descriptor for w and mask
) ;
```

`GrB_Vector_assign_<type>` assigns a single scalar to an entire subvector of the vector `w`. The operation is exactly like setting a single entry in an `n`-by-1 matrix,  $A(I,0) = x$ , where the column index for a vector is implicitly `j=0`. The mask vector has the same size as `w`. If `x` is a `GrB_Scalar`, the nonpolymorphic name of the method is `GrB_Vector_assign_Scalar`. For further details of this function, see `GrB_Matrix_assign_<type>` in the next section (12.8.11). Following the C API Specification, results are well-defined if `I` contains duplicate indices. Duplicate indices are simply ignored. See Section 12.10 for more details.

### 12.8.10 GxB\_Vector\_assign\_Scalar\_Vector: assign a scalar to a subvector

```
GrB_Info GrB_assign          // w<mask>(I) = accum (w(I),x)
(
    GrB_Vector w,             // input/output vector for results
    const GrB_Vector mask,    // optional mask for w, unused if NULL
    const GrB_BinaryOp accum, // optional accum for Z=accum(w(I),x)
    const GrB_Scalar x,       // scalar to assign to w(I)
    const GrB_Vector I_vector, // row indices
    const GrB_Descriptor desc
) ;
```

`GxB_Vector_assign_Scalar_Vector` is identical to `GrB_Vector_assign_Scalar`, except that the row indices are given by the `GrB_Vector` `I` with `ni` entries. The interpretation of `I_vector` is controlled by descriptor setting `GxB_ROWINDEX_LIST`. The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.8.11 GrB\_Matrix\_assign\_<type>: assign a scalar to a submatrix

```
GrB_Info GrB_assign          // C<Mask>(I,J) = accum (C(I,J),x)
(
    GrB_Matrix C,             // input/output matrix for results
    const GrB_Matrix Mask,    // optional mask for C, unused if NULL
    const GrB_BinaryOp accum, // optional accum for Z=accum(C(I,J),x)
    const <type> x,           // scalar to assign to C(I,J)
    const GrB_Index *I,       // row indices
    const GrB_Index ni,       // number of row indices
    const GrB_Index *J,       // column indices
    const GrB_Index nj,       // number of column indices
    const GrB_Descriptor desc // descriptor for C and Mask
) ;
```

`GrB_Matrix_assign_<type>` assigns a single scalar to an entire submatrix of `C`, like the *scalar expansion*  $C(I,J)=x$  in MATLAB. The scalar `x` is implicitly expanded into a matrix `A` of size `ni` by `nj`, and then the matrix `A` is assigned to `C(I,J)` using the same method as in `GrB_Matrix_assign`. Refer to that function in Section 12.8.3 for further details.

The `Mask` has the same size as `C`.

For the accumulation step, the scalar `x` is typecasted directly into the type of `C` when the `accum` operator is not applied to it, or into the `ytype`

of the `accum` operator, if `accum` is not `NULL`, for entries that are already present in `C`.

The `<type> x` notation is otherwise the same as `GrB_Matrix_setElement` (see Section 6.10.12). Any value can be passed to this function and its type will be detected, via the `_Generic` feature of C11. For a user-defined type, `x` is a `void *` pointer that points to a memory space holding a single entry of a scalar that has exactly the same user-defined type as the matrix `C`. This user-defined type must exactly match the user-defined type of `C` since no typecasting is done between user-defined types.

If a `void *` pointer is passed in and the type of the underlying scalar does not exactly match the user-defined type of `C`, then results are undefined. No error status will be returned since GraphBLAS has no way of catching this error.

If `x` is a `GrB_Scalar`, the nonpolymorphic name of the method is `GrB_Matrix_assign_Scalar`. In this case, if `x` has no entry, then it is implicitly expanded into a matrix `A` of size `ni` by `nj`, with no entries present.

Following the C API Specification, results are well-defined if `I` or `J` contain duplicate indices. Duplicate indices are simply ignored. See Section 12.10 for more details.

**Performance considerations:** If `A` is not transposed: if `|I|` is small, then it is fastest if the format of `C` is `GrB_ROWMAJOR`; if `|J|` is small, then it is fastest if the format of `C` is `GrB_COLMAJOR`. The opposite is true if `A` is transposed.

#### 12.8.12 `GxB_Matrix_assign_Scalar_Vector`: assign a scalar to a submatrix

```
GrB_Info GrB_assign           // C<Mask>(I,J) = accum (C(I,J),x)
(
    GrB_Matrix C,             // input/output matrix for results
    const GrB_Matrix Mask,    // optional mask for C, unused if NULL
    const GrB_BinaryOp accum, // optional accum for Z=accum(C(I,J),x)
    const GrB_Scalar x,       // scalar to assign to C(I,J)
    const GrB_Vector I_vector, // row indices
    const GrB_Vector J_vector, // column indices
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_assign_Scalar_Vector` is identical to `GrB_Matrix_assign_Scalar`, except that the row indices are given by the `GrB_Vector` `I` with `ni` entries,

and the column indices are given by the `GrB_Vector J` with `nj` entries. The interpretation of `I_vector` and `J_vector` are controlled by descriptor setting `GxB_ROWINDEX_LIST` and `GxB_COLINDEX_LIST`, respectively. The method can use either the indices or values of each of the input vectors, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section [6.16.4](#) for details.

## 12.9 GxB\_subassign: submatrix assignment

The methods described in this section are all variations of the form  $C(I, J) = A$ , which modifies a submatrix of the matrix  $C$ . All methods can be used in their generic form with the single name `GxB_subassign`. This is reflected in the prototypes. However, to avoid confusion between the different kinds of assignment, the name of the specific function is used when describing each variation. If the discussion applies to all variations, the simple name `GxB_subassign` is used.

See Section 11 for a description of the row indices  $I$  and  $ni$ , and the column indices  $J$  and  $nj$ .

`GxB_subassign` is very similar to `GrB_assign`, described in Section 12.8. The two operations are compared and contrasted in Section 12.11. For a discussion of how duplicate indices are handled in  $I$  and  $J$ , see Section 12.10.

### 12.9.1 GxB\_Vector\_subassign: assign to a subvector

```
GrB_Info GxB_subassign          // w(I)<mask> = accum (w(I),u)
(
    GrB_Vector w,                // input/output vector for results
    const GrB_Vector mask,       // optional mask for w(I), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(w(I),t)
    const GrB_Vector u,          // first input: vector u
    const GrB_Index *I,          // row indices
    const GrB_Index ni,          // number of row indices
    const GrB_Descriptor desc     // descriptor for w(I) and mask
) ;
```

`GxB_Vector_subassign` operates on a subvector  $w(I)$  of  $w$ , modifying it with the vector  $u$ . The method is identical to `GxB_Matrix_subassign` described in Section 12.9.3, where all matrices have a single column each. The `mask` has the same size as  $w(I)$  and  $u$ . The only other difference is that the input  $u$  in this method is not transposed via the `GrB_INP0` descriptor.

### 12.9.2 GxB\_Vector\_subassign\_Vector: assign to a subvector

```
GrB_Info GxB_subassign          // w(I)<mask> = accum (w(I),u)
(
    GrB_Vector w,                // input/output vector for results
    const GrB_Vector mask,       // optional mask for w(I), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(w(I),t)
    const GrB_Vector u,          // first input: vector u
    const GrB_Vector I_vector,   // row indices
    const GrB_Descriptor desc
) ;
```

`GxB_Vector_subassign_Vector` is identical to `GxB_Vector_subassign`, except that the row indices are given by the `GrB_Vector` `I` with `ni` entries. The interpretation of `I_vector` is controlled by descriptor setting `GxB_ROWINDEX_LIST`. The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.9.3 GxB\_Matrix\_subassign: assign to a submatrix

```
GrB_Info GxB_subassign          // C(I,J)<Mask> = accum (C(I,J),A)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // optional mask for C(I,J), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(C(I,J),T)
    const GrB_Matrix A,          // first input: matrix A
    const GrB_Index *I,          // row indices
    const GrB_Index ni,          // number of row indices
    const GrB_Index *J,          // column indices
    const GrB_Index nj,          // number of column indices
    const GrB_Descriptor desc     // descriptor for C(I,J), Mask, and A
) ;
```

`GxB_Matrix_subassign` operates only on a submatrix `S` of `C`, modifying it with the matrix `A`. For this operation, the result is not the entire matrix `C`, but a submatrix `S=C(I,J)` of `C`. The steps taken are as follows, except that `A` may be optionally transposed via the `GrB_INPO` descriptor option.

Step	GraphBLAS notation	description
1	$\mathbf{S} = \mathbf{C}(\mathbf{I}, \mathbf{J})$	extract the $\mathbf{C}(\mathbf{I}, \mathbf{J})$ submatrix
2	$\mathbf{S}\langle\mathbf{M}\rangle = \mathbf{S} \odot \mathbf{A}$	apply the accumulator/mask to the submatrix $\mathbf{S}$
3	$\mathbf{C}(\mathbf{I}, \mathbf{J}) = \mathbf{S}$	put the submatrix $\mathbf{S}$ back into $\mathbf{C}(\mathbf{I}, \mathbf{J})$

The accumulator/mask step in Step 2 is the same as for all other GraphBLAS operations, described in Section 2.3, except that for `GxB_subassign`, it is applied to just the submatrix  $\mathbf{S} = \mathbf{C}(\mathbf{I}, \mathbf{J})$ , and thus the `Mask` has the same size as  $\mathbf{A}$ ,  $\mathbf{S}$ , and  $\mathbf{C}(\mathbf{I}, \mathbf{J})$ .

The `GxB_subassign` operation is the reverse of matrix extraction:

- For submatrix extraction, `GrB_Matrix_extract`, the submatrix  $\mathbf{A}(\mathbf{I}, \mathbf{J})$  appears on the right-hand side of the assignment,  $\mathbf{C}=\mathbf{A}(\mathbf{I}, \mathbf{J})$ , and entries outside of the submatrix are not accessed and do not take part in the computation.
- For submatrix assignment, `GxB_Matrix_subassign`, the submatrix  $\mathbf{C}(\mathbf{I}, \mathbf{J})$  appears on the left-hand-side of the assignment,  $\mathbf{C}(\mathbf{I}, \mathbf{J})=\mathbf{A}$ , and entries outside of the submatrix are not accessed and do not take part in the computation.

In both methods, the accumulator and mask modify the submatrix of the assignment; they simply differ on which side of the assignment the submatrix resides on. In both cases, if the `Mask` matrix is present it is the same size as the submatrix:

- For submatrix extraction,  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}(\mathbf{I}, \mathbf{J})$  is computed, where the submatrix is on the right. The mask  $\mathbf{M}$  has the same size as the submatrix  $\mathbf{A}(\mathbf{I}, \mathbf{J})$ .
- For submatrix assignment,  $\mathbf{C}(\mathbf{I}, \mathbf{J})\langle\mathbf{M}\rangle = \mathbf{C}(\mathbf{I}, \mathbf{J}) \odot \mathbf{A}$  is computed, where the submatrix is on the left. The mask  $\mathbf{M}$  has the same size as the submatrix  $\mathbf{C}(\mathbf{I}, \mathbf{J})$ .

In Step 1, the submatrix  $\mathbf{S}$  is first computed by the `GrB_Matrix_extract` operation,  $\mathbf{S}=\mathbf{C}(\mathbf{I}, \mathbf{J})$ .

Step 2 accumulates the results  $\mathbf{S}\langle\mathbf{M}\rangle = \mathbf{S} \odot \mathbf{T}$ , exactly as described in Section 2.3, but operating on the submatrix  $\mathbf{S}$ , not  $\mathbf{C}$ , using the optional

**Mask** and **accum** operator. The matrix **T** is simply  $\mathbf{T} = \mathbf{A}$ , or  $\mathbf{T} = \mathbf{A}^T$  if **A** is transposed via the **desc** descriptor, **GrB\_INP0**. The **GrB\_REPLACE** option in the descriptor clears **S** after computing  $\mathbf{Z} = \mathbf{T}$  or  $\mathbf{Z} = \mathbf{C} \odot \mathbf{T}$ , not all of **C** since this operation can only modify the specified submatrix of **C**.

Finally, Step 3 writes the result (which is the modified submatrix **S** and not all of **C**) back into the **C** matrix that contains it, via the assignment  $\mathbf{C}(\mathbf{I}, \mathbf{J}) = \mathbf{S}$ , using the reverse operation from the method described for matrix extraction:

```

for i = 1:ni
    for j = 1:nj
        if (S(i,j).pattern)
            C(I(i),J(j)).matrix = S(i,j).matrix ;
            C(I(i),J(j)).pattern = true ;
        end
    end
end
end

```

**Performance considerations:** If **A** is not transposed: if  $|\mathbf{I}|$  is small, then it is fastest if the format of **C** is **GrB\_ROWMAJOR**; if  $|\mathbf{J}|$  is small, then it is fastest if the format of **C** is **GrB\_COLMAJOR**. The opposite is true if **A** is transposed.

#### 12.9.4 GxB\_Matrix\_subassign\_Vector: assign to a submatrix

```

GrB_Info GxB_subassign          // C(I,J)<Mask> = accum (C(I,J),A)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // mask for C(I,J), unused if NULL
    const GrB_BinaryOp accum,    // accum for Z=accum(C(I,J),T)
    const GrB_Matrix A,          // first input:  matrix A
    const GrB_Vector I_vector,   // row indices
    const GrB_Vector J_vector,   // column indices
    const GrB_Descriptor desc
) ;

```

**GxB\_Matrix\_subassign\_Vector** is identical to **GxB\_Matrix\_subassign**, except that the row indices are given by the **GrB\_Vector** **I** with **ni** entries, and the column indices are given by the **GrB\_Vector** **J** with **nj** entries. The interpretation of **I\_vector** and **J\_vector** are controlled by descriptor setting **GxB\_ROWINDEX\_LIST** and **GxB\_COLINDEX\_LIST**, respectively. The method can use either the indices or values of each of the input vectors, or it can use

the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.9.5 GxB\_Col\_subassign: assign to a sub-column of a matrix

```
GrB_Info GxB_subassign          // C(I,j)<mask> = accum (C(I,j),u)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Vector mask,       // optional mask for C(I,j), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(C(I,j),t)
    const GrB_Vector u,          // input vector
    const GrB_Index *I,          // row indices
    const GrB_Index ni,          // number of row indices
    const GrB_Index j,           // column index
    const GrB_Descriptor desc     // descriptor for C(I,j) and mask
) ;
```

`GxB_Col_subassign` modifies a single sub-column of a matrix `C`. It is the same as `GxB_Matrix_subassign` where the index vector `J[0]=j` is a single column index (and thus `nj=1`), and where all matrices in `GxB_Matrix_subassign` (except `C`) consist of a single column. The `mask` vector has the same size as `u` and the sub-column `C(I,j)`. The input descriptor `GrB_INP0` is ignored; the input vector `u` is not transposed. Refer to `GxB_Matrix_subassign` for further details.

**Performance considerations:** `GxB_Col_subassign` is much faster than `GxB_Row_subassign` if the format of `C` is `GrB_COLMAJOR`. `GxB_Row_subassign` is much faster than `GxB_Col_subassign` if the format of `C` is `GrB_ROWMAJOR`.

### 12.9.6 GxB\_Col\_subassign\_Vector: assign to a sub-column of a matrix

```
GrB_Info GxB_subassign          // C(I,j)<mask> = accum (C(I,j),u)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Vector mask,       // optional mask for C(I,j), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(C(I,j),t)
    const GrB_Vector u,          // input vector
    const GrB_Vector I_vector,   // row indices
    const GrB_Index j,           // column index
    const GrB_Descriptor desc
) ;
```

`GxB_Col_subassign_Vector` is identical to `GxB_Col_subassign`, except that the row indices are given by the `GrB_Vector I` with `ni` entries. The interpretation of `I_vector` is controlled by descriptor setting `GxB_ROWINDEX_LIST`. The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.9.7 GxB\_Row\_subassign: assign to a sub-row of a matrix

```
GrB_Info GxB_subassign          // C(i,J)<mask'> = accum (C(i,J),u')
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Vector mask,       // optional mask for C(i,J), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for z=accum(C(i,J),t)
    const GrB_Vector u,         // input vector
    const GrB_Index i,          // row index
    const GrB_Index *J,         // column indices
    const GrB_Index nj,         // number of column indices
    const GrB_Descriptor desc    // descriptor for C(i,J) and mask
) ;
```

`GxB_Row_subassign` modifies a single sub-row of a matrix `C`. It is the same as `GxB_Matrix_subassign` where the index vector `I[0]=i` is a single row index (and thus `ni=1`), and where all matrices in `GxB_Matrix_subassign` (except `C`) consist of a single row. The `mask` vector has the same size as `u` and the sub-column `C(I,j)`. The input descriptor `GrB_INP0` is ignored; the input vector `u` is not transposed. Refer to `GxB_Matrix_subassign` for further details.

**Performance considerations:** `GxB_Col_subassign` is much faster than `GxB_Row_subassign` if the format of `C` is `GrB_COLMAJOR`. `GxB_Row_subassign` is much faster than `GxB_Col_subassign` if the format of `C` is `GrB_ROWMAJOR`.

### 12.9.8 GxB\_Row\_subassign\_Vector: assign to a sub-row of a matrix

```
GrB_Info GxB_Row_subassign_Vector    // C(i,J)<mask> = accum (C(i,J),u')
(
    GrB_Matrix C,                    // input/output matrix for results
    const GrB_Vector mask,           // optional mask for C(i,J), unused if NULL
    const GrB_BinaryOp accum,        // optional accum for z=accum(C(i,J),t)
    const GrB_Vector u,              // input vector
    const GrB_Index i,               // row index
    const GrB_Vector J_vector,       // column indices
    const GrB_Descriptor desc
) ;
```

`GxB_Row_subassign_Vector` is identical to `GrB_Row_subassign`, except that the column indices are given by the `GrB_Vector` `J` with `nj` entries. The interpretation of `J_vector` is controlled by descriptor setting `GxB_COLINDEX_LIST`. The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.9.9 GxB\_Vector\_subassign\_<type>: assign a scalar to a subvector

```
GrB_Info GxB_subassign                // w(I)<mask> = accum (w(I),x)
(
    GrB_Vector w,                    // input/output vector for results
    const GrB_Vector mask,           // optional mask for w(I), unused if NULL
    const GrB_BinaryOp accum,        // optional accum for z=accum(w(I),x)
    const <type> x,                  // scalar to assign to w(I)
    const GrB_Index *I,              // row indices
    const GrB_Index ni,              // number of row indices
    const GrB_Descriptor desc        // descriptor for w(I) and mask
) ;
```

`GxB_Vector_subassign_<type>` assigns a single scalar to an entire subvector of the vector `w`. The operation is exactly like setting a single entry in an `n`-by-1 matrix,  $A(I,0) = x$ , where the column index for a vector is implicitly `j=0`. If `x` is a `GrB_Scalar`, the nonpolymorphic name of the method is `GxB_Vector_subassign_Scalar`. For further details of this function, see `GxB_Matrix_subassign_<type>` in Section 12.9.11.

### 12.9.10 GxB\_Vector\_subassign\_Scalar\_Vector: assign a scalar to a sub-vector

```
GrB_Info GxB_subassign          // w(I)<mask> = accum (w(I),x)
(
    GrB_Vector w,                // input/output vector for results
    const GrB_Vector mask,       // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(w(I),x)
    const GrB_Scalar scalar,     // scalar to assign to w(I)
    const GrB_Vector I_vector,   // row indices
    const GrB_Descriptor desc
) ;
```

`GxB_Vector_subassign_Scalar_Vector` is identical to `GxB_Vector_subassign_Scalar`, except that the row indices are given by the `GrB_Vector` `I` with `ni` entries. The interpretation of `I_vector` is controlled by descriptor setting `GxB_ROWINDEX_LIST`. The method can use either the indices or values of the input vector, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section 6.16.4 for details.

### 12.9.11 GxB\_Matrix\_subassign\_<type>: assign a scalar to a submatrix

```
GrB_Info GxB_subassign          // C(I,J)<Mask> = accum (C(I,J),x)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // optional mask for C(I,J), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(C(I,J),x)
    const <type> x,              // scalar to assign to C(I,J)
    const GrB_Index *I,          // row indices
    const GrB_Index ni,          // number of row indices
    const GrB_Index *J,          // column indices
    const GrB_Index nj,          // number of column indices
    const GrB_Descriptor desc    // descriptor for C(I,J) and Mask
) ;
```

`GxB_Matrix_subassign_<type>` assigns a single scalar to an entire sub-matrix of `C`, like the *scalar expansion* `C(I,J)=x` in MATLAB. The scalar `x` is implicitly expanded into a matrix `A` of size `ni` by `nj`, with all entries present and equal to `x`, and then the matrix `A` is assigned to `C(I,J)` using the same method as in `GxB_Matrix_subassign`. Refer to that function in Section 12.9.3 for further details. For the accumulation step, the scalar `x` is typecasted directly into the type of `C` when the `accum` operator is not applied

to it, or into the `ytype` of the `accum` operator, if `accum` is not `NULL`, for entries that are already present in `C`.

The `<type> x` notation is otherwise the same as `GrB_Matrix_setElement` (see Section 6.10.12). Any value can be passed to this function and its type will be detected, via the `_Generic` feature of C11. For a user-defined type, `x` is a `void *` pointer that points to a memory space holding a single entry of a scalar that has exactly the same user-defined type as the matrix `C`. This user-defined type must exactly match the user-defined type of `C` since no typecasting is done between user-defined types.

If a `void *` pointer is passed in and the type of the underlying scalar does not exactly match the user-defined type of `C`, then results are undefined. No error status will be returned since GraphBLAS has no way of catching this error.

If `x` is a `GrB_Scalar`, the nonpolymorphic name of the method is `GxB_Matrix_subassign_Scalar`. In this case, if `x` has no entry, then it is implicitly expanded into a matrix `A` of size `ni` by `nj`, with no entries present.

**Performance considerations:** If `A` is not transposed: if `|I|` is small, then it is fastest if the format of `C` is `GrB_ROWMAJOR`; if `|J|` is small, then it is fastest if the format of `C` is `GrB_COLMAJOR`. The opposite is true if `A` is transposed.

#### 12.9.12 `GxB_Matrix_subassign_Scalar_Vector`: assign a scalar to a sub-matrix

```
GrB_Info GxB_subassign          // C(I,J)<Mask> = accum (C(I,J),x)
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // optional mask for C(I,J), unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(C(I,J),x)
    const GrB_Scalar scalar,     // scalar to assign to C(I,J)
    const GrB_Vector I_vector,   // row indices
    const GrB_Vector J_vector,   // column indices
    const GrB_Descriptor desc
) ;
```

`GxB_Matrix_subassign_Scalar_Vector` is identical to `GxB_Matrix_subassign_Scalar`, except that the row indices are given by the `GrB_Vector I` with `ni` entries, and the column indices are given by the `GrB_Vector J` with `nj` entries. The interpretation of `I_vector` and `J_vector` are controlled by descriptor setting `GxB_ROWINDEX_LIST` and `GxB_COLINDEX_LIST`, respectively. The method can

use either the indices or values of each of the input vectors, or it can use the values as a stride (`lo:inc:hi`); the default is to use the values. See Section [6.16.4](#) for details.

## 12.10 Duplicate indices in GrB\_assign and GxB\_subassign

According to the GraphBLAS C API Specification if the index vectors I or J contain duplicate indices, the results are undefined for GrB\_Matrix\_assign, GrB\_Matrix\_assign, GrB\_Col\_assign, and GrB\_Row\_assign. Only the scalar assignment operations (GrB\_Matrix\_assign\_TYPE and GrB\_Matrix\_assign\_TYPE) are well-defined when duplicates appear in I and J. In those two functions, duplicate indices are ignored.

As an extension to the specification, SuiteSparse:GraphBLAS provides a definition of how duplicate indices are handled in all cases. If I has duplicate indices, they are ignored and the last unique entry in the list is used. When no mask and no accumulator is present, the results are identical to how MATLAB handles duplicate indices in the built-in expression  $C(I, J) = A$ . Details of how this is done is shown below.

```
function C = subassign (C, I, J, A)
% submatrix assignment with pre-sort of I and J; and remove duplicates

% delete duplicates from I, keeping the last one seen
[I2 I2k] = sort (I) ;
Idupl = [(I2 (1:end-1) == I2 (2:end)), false] ;
I2 = I2 (~Idupl) ;
I2k = I2k (~Idupl) ;
assert (isequal (I2, unique (I)))

% delete duplicates from J, keeping the last one seen
[J2 J2k] = sort (J) ;
Jdupl = [(J2 (1:end-1) == J2 (2:end)), false] ;
J2 = J2 (~Jdupl) ;
J2k = J2k (~Jdupl) ;
assert (isequal (J2, unique (J)))

% do the submatrix assignment, with no duplicates in I2 or J2
C (I2,J2) = A (I2k,J2k) ;
```

If a mask is present, then it is replaced with  $M = M(I2k, J2k)$  for GxB\_subassign, or with  $M = M(I2, J2)$  for GrB\_assign. If an accumulator operator is present, it is applied after the duplicates are removed, as (for example):

```
C (I2,J2) = C (I2,J2) + A (I2k,J2k) ;
```

These definitions allow the MATLAB/Octave interface to GraphBLAS to return the same results for  $C(I, J)=A$  for a GrB object as they do for built-in MATLAB/Octave matrices. They also allow the assignment to be done in parallel.

Results are always well-defined in SuiteSparse:GraphBLAS, but they might not be what you expect. For example, suppose the MIN operator is being used the following assignment to the vector  $x$ , and suppose  $I$  contains the entries  $[0\ 0]$ . Suppose  $x$  is initially empty, of length 1, and suppose  $y$  is a vector of length 2 with the values  $[5\ 7]$ .

```
#include "GraphBLAS.h"
#undef I      /* complex.h #define's I, but I is used an array below */
#include <stdio.h>
int main (void)
{
    GrB_init (GrB_NONBLOCKING) ;
    GrB_Vector x, y ;
    GrB_Vector_new (&x, GrB_INT32, 1) ;
    GrB_Vector_new (&y, GrB_INT32, 2) ;
    GrB_Index I [2] = {0, 0} ;
    GrB_Vector_setElement (y, 5, 0) ;
    GrB_Vector_setElement (y, 7, 1) ;
    GrB_Vector_wait (&y) ;
    GxB_print (x, 3) ;
    GxB_print (y, 3) ;
    GrB_assign (x, NULL, GrB_MIN_INT32, y, I, 2, NULL) ;
    GrB_Vector_wait (&y) ;
    GxB_print (x, 3) ;
    GrB_finalize ( ) ;
}
```

You might (wrongly) expect the result to be the vector  $x(0)=5$ , since two entries seem to be assigned, and the min operator might be expected to take the minimum of the two. This is not how SuiteSparse:GraphBLAS handles duplicates.

Instead, the first duplicate index of  $I$  is discarded ( $I[0] = 0$ , and  $y(0)=5$ ). and only the second entry is used ( $I[1] = 0$ , and  $y(1)=7$ ). The output of the above program is:

1x1 GraphBLAS int32\_t vector, sparse by col:  
x, no entries

2x1 GraphBLAS int32\_t vector, sparse by col:  
y, 2 entries

(0,0) 5  
(1,0) 7

1x1 GraphBLAS int32\_t vector, sparse by col:  
x, 1 entry

(0,0) 7

You see that the result is  $x(0)=7$ , since the  $y(0)=5$  entry has been ignored because of the duplicate indices in  $I$ .

**SPEC:** Providing a well-defined behavior for duplicate indices with matrix and vector assignment is an extension to the specification. The specification only defines the behavior when assigning a scalar into a matrix or vector, and states that duplicate indices otherwise lead to undefined results.

## 12.11 Comparing GrB\_assign and GxB\_subassign

The GxB\_subassign and GrB\_assign operations are very similar, but they differ in two ways:

1. **The Mask has a different size:** The mask in GxB\_subassign has the same dimensions as  $w(I)$  for vectors and  $C(I,J)$  for matrices. In GrB\_assign, the mask is the same size as  $w$  or  $C$ , respectively (except for the row/col variants). The two masks are related. If  $M$  is the mask for GrB\_assign, then  $M(I,J)$  is the mask for GxB\_subassign. If there is no mask, or if  $I$  and  $J$  are both GrB\_ALL, the two masks are the same. For GrB\_Row\_assign and GrB\_Col\_assign, the mask vector is the same size as a row or column of  $C$ , respectively. For the corresponding GxB\_Row\_subassign and GxB\_Col\_subassign operations, the mask is the same size as the sub-row  $C(i,J)$  or subcolumn  $C(I,j)$ , respectively.
2. **GrB\_REPLACE is different:** They differ in how  $C$  is affected in areas outside the  $C(I,J)$  submatrix. In GxB\_subassign, the  $C(I,J)$  submatrix is the only part of  $C$  that can be modified, and no part of  $C$  outside the submatrix is ever modified. In GrB\_assign, it is possible to delete entries in  $C$  outside the submatrix, but only in one specific manner. Suppose the mask  $M$  is present (or, suppose it is not present but GrB\_COMP is true). After (optionally) complementing the mask, the value of  $M(i,j)$  can be 0 for some entry outside the  $C(I,J)$  submatrix. If the GrB\_REPLACE descriptor is true, GrB\_assign deletes this entry.

GxB\_subassign and GrB\_assign are identical if GrB\_REPLACE is set to its default value of false, and if the masks happen to be the same. The two masks can be the same in two cases: either the Mask input is NULL (and it is not complemented via GrB\_COMP), or  $I$  and  $J$  are both GrB\_ALL. If all these conditions hold, the two algorithms are identical and have the same performance. Otherwise, GxB\_subassign is much faster than GrB\_assign when the latter must examine the entire matrix  $C$  to delete entries (when GrB\_REPLACE is true), and if it must deal with a much larger Mask matrix. However, both methods have specific uses.

Consider using  $C(I,J) += F$  for many submatrices  $F$  (for example, when assembling a finite-element matrix). If the Mask is meant as a specification for which entries of  $C$  should appear in the final result, then use GrB\_assign.

If instead the **Mask** is meant to control which entries of the submatrix  $C(I, J)$  are modified by the finite-element **F**, then use **GxB\_subassign**. This is particularly useful if the **Mask** is a template that follows along with the finite-element **F**, independent of where it is applied to **C**. Using **GrB\_assign** would be very difficult in this case since a new **Mask**, the same size as **C**, would need to be constructed for each finite-element **F**.

In GraphBLAS notation, the two methods can be described as follows:

matrix and vector subassign	$C(I, J)\langle M \rangle = C(I, J) \odot A$
matrix and vector assign	$C\langle M \rangle(I, J) = C(I, J) \odot A$

This notation does not include the details of the **GrB\_COMP** and **GrB\_REPLACE** descriptors, but it does illustrate the difference in the **Mask**. In the subassign, **Mask** is the same size as  $C(I, J)$  and **A**. If  $I[0]=i$  and  $J[0]=j$ , Then  $Mask(0,0)$  controls how  $C(i, j)$  is modified by the subassign, from the value  $A(0,0)$ . In the assign, **Mask** is the same size as **C**, and  $Mask(i, j)$  controls how  $C(i, j)$  is modified.

The **GxB\_subassign** and **GrB\_assign** functions have the same signatures; they differ only in how they consider the **Mask** and the **GrB\_REPLACE** descriptor

Details of each step of the two operations are listed below:

Step	GrB_Matrix_assign	GxB_Matrix_subassign
1	$S = C(I, J)$	$S = C(I, J)$
2	$S = S \odot A$	$S\langle M \rangle = S \odot A$
3	$Z = C$	$C(I, J) = S$
4	$Z(I, J) = S$	
5	$C\langle M \rangle = Z$	

Step 1 is the same. In the Accumulator Phase (Step 2), the expression  $S \odot A$ , described in Section 2.3, is the same in both operations. The result is simply **A** if **accum** is **NULL**. It only applies to the submatrix **S**, not the whole matrix. The result  $S \odot A$  is used differently in the Mask/Replace phase.

The Mask/Replace Phase, described in Section 2.3 is different:

- For **GrB\_assign** (Step 5), the mask is applied to all of **C**. The mask has the same size as **C**. Just prior to making the assignment via the mask, the **GrB\_REPLACE** option can be used to clear all of **C** first. This is the only way in which entries in **C** that are outside the  $C(I, J)$  submatrix can be modified by this operation.

- For `GxB_subassign` (Step 2b), the mask is applied to just **S**. The mask has the same size as  $\mathbf{C}(\mathbf{I}, \mathbf{J})$ , **S**, and **A**. Just prior to making the assignment via the mask, the `GrB_REPLACE` option can be used to clear **S** first. No entries in **C** that are outside the  $\mathbf{C}(\mathbf{I}, \mathbf{J})$  can be modified by this operation. Thus, `GrB_REPLACE` has no effect on entries in **C** outside the  $\mathbf{C}(\mathbf{I}, \mathbf{J})$  submatrix.

The differences between `GrB_assign` and `GxB_subassign` can be seen in Tables 5 and 6. The first table considers the case when the entry  $c_{ij}$  is in the  $\mathbf{C}(\mathbf{I}, \mathbf{J})$  submatrix, and it describes what is computed for both `GrB_assign` and `GxB_subassign`. They perform the exact same computation; the only difference is how the value of the mask is specified. Compare Table 5 with Table 1 in Section 7.

The first column of Table 5 is *yes* if `GrB_REPLACE` is enabled, and a dash otherwise. The second column is *yes* if an accumulator operator is given, and a dash otherwise. The third column is  $c_{ij}$  if the entry is present in **C**, and a dash otherwise. The fourth column is  $a_{i'j'}$  if the corresponding entry is present in **A**, where  $i = \mathbf{I}(i')$  and  $j = \mathbf{J}(j')$ .

The *mask* column is 1 if the effective value of the mask allows **C** to be modified, and 0 otherwise. This is  $m_{ij}$  for `GrB_assign`, and  $m_{i'j'}$  for `GxB_subassign`, to reflect the difference in the mask, but this difference is not reflected in the table. The value 1 or 0 is the value of the entry in the mask after it is optionally complemented via the `GrB_COMP` option.

Finally, the last column is the action taken in this case. It is left blank if no action is taken, in which case  $c_{ij}$  is not modified if present, or not inserted into **C** if not present.

repl	accum	<b>C</b>	<b>A</b>	mask	action taken by GrB_assign and GxB_subassign

yes	yes	-	-	0	

Table 6: Results of `assign` for entries outside the  $\mathbf{C}(\mathbf{I}, \mathbf{J})$  submatrix. Sub-assign has no effect on these entries.

Table 6 illustrates how `GrB_assign` and `GxB_subassign` differ for entries outside the submatrix. `GxB_subassign` never modifies any entry outside the  $\mathbf{C}(\mathbf{I}, \mathbf{J})$  submatrix, but `GrB_assign` can modify them in two cases listed in Table 6. When the `GrB_REPLACE` option is selected, and when the `Mask(i, j)` for an entry  $c_{ij}$  is false (or if the `Mask(i, j)` is true and `GrB_COMP` is enabled via the descriptor), then the entry is deleted by `GrB_assign`.

The fourth column of Table 6 differs from Table 5, since entries in  $\mathbf{A}$  never affect these entries. Instead, for all index pairs outside the  $I \times J$  submatrix,  $\mathbf{C}$  and  $\mathbf{Z}$  are identical (see Step 3 above). As a result, each section of the table includes just two cases: either  $c_{ij}$  is present, or not. This in contrast to Table 5, where each section must consider four different cases.

The `GrB_Row_assign` and `GrB_Col_assign` operations are slightly different. They only affect a single row or column of  $\mathbf{C}$ . For `GrB_Row_assign`, Table 6 only applies to entries in the single row  $\mathbf{C}(\mathbf{i}, \mathbf{J})$  that are outside the list of indices,  $\mathbf{J}$ . For `GrB_Col_assign`, Table 6 only applies to entries in the single column  $\mathbf{C}(\mathbf{I}, \mathbf{j})$  that are outside the list of indices,  $\mathbf{I}$ .

### 12.11.1 Example

The difference between `GxB_subassign` and `GrB_assign` is illustrated in the following example. Consider the 2-by-2 matrix **C** where all entries are present.

$$\mathbf{C} = \begin{bmatrix} 11 & 12 \\ 21 & 22 \end{bmatrix}$$

Suppose `GrB_REPLACE` is true, and `GrB_COMP` is false. Let the `Mask` be:

$$\mathbf{M} = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix}.$$

Let **A** = 100, and let the index sets be **I** = 0 and **J** = 1. Consider the computation  $\mathbf{C}(\mathbf{M})(0,1) = \mathbf{C}(0,1) + \mathbf{A}$ , using the `GrB_assign` operation. The result is:

$$\mathbf{C} = \begin{bmatrix} 11 & 112 \\ - & 22 \end{bmatrix}.$$

The (0,1) entry is updated and the (1,0) entry is deleted because its `Mask` is zero. The other two entries are not modified since **Z** = **C** outside the submatrix, and those two values are written back into **C** because their `Mask` values are 1. The (1,0) entry is deleted because the entry **Z**(1,0) = 21 is prevented from being written back into **C** since `Mask`(1,0)=0.

Now consider the analogous `GxB_subassign` operation. The `Mask` has the same size as **A**, namely:

$$\mathbf{M} = \begin{bmatrix} 1 \end{bmatrix}.$$

After computing  $\mathbf{C}(0,1)(\mathbf{M}) = \mathbf{C}(0,1) + \mathbf{A}$ , the result is

$$\mathbf{C} = \begin{bmatrix} 11 & 112 \\ 21 & 22 \end{bmatrix}.$$

Only the **C**(**I**,**J**) submatrix, the single entry **C**(0,1), is modified by `GxB_subassign`. The entry **C**(1,0) = 21 is unaffected by `GxB_subassign`, but it is deleted by `GrB_assign`.

### 12.11.2 Performance of `GxB_subassign`, `GrB_assign` and `GrB*_setElement`

When SuiteSparse:GraphBLAS uses non-blocking mode, the modifications to a matrix by `GxB_subassign`, `GrB_assign`, and `GrB*_setElement` can be postponed, and computed all at once later on. This has a huge impact on performance.

A sequence of assignments is fast if their completion can be postponed for as long as possible, or if they do not modify the pattern at all. Modifying the pattern can be costly, but it is fast if non-blocking mode can be fully exploited.

Consider a sequence of  $t$  submatrix assignments  $\mathbf{C}(\mathbf{I}, \mathbf{J}) = \mathbf{C}(\mathbf{I}, \mathbf{J}) + \mathbf{A}$  to an  $n$ -by- $n$  matrix  $\mathbf{C}$  where each submatrix  $\mathbf{A}$  has size  $a$ -by- $a$  with  $s$  entries, and where  $\mathbf{C}$  starts with  $c$  entries. Assume the matrices are all stored in non-hypersparse form, by row (`GrB_ROWMAJOR`).

If blocking mode is enabled, or if the sequence requires the matrix to be completed after each assignment, each of the  $t$  assignments takes  $O(a + s \log n)$  time to process the  $\mathbf{A}$  matrix and then  $O(n + c + s \log s)$  time to complete  $\mathbf{C}$ . The latter step uses `GrB*_build` to build an update matrix and then merge it with  $\mathbf{C}$ . This step does not occur if the sequence of assignments does not add new entries to the pattern of  $\mathbf{C}$ , however. Assuming in the worst case that the pattern does change, the total time is  $O(t[a + s \log n + n + c + s \log s])$ .

If the sequence can be computed with all updates postponed until the end of the sequence, then the total time is no worse than  $O(a + s \log n)$  to process each  $\mathbf{A}$  matrix, for  $t$  assignments, and then a single `build` at the end, taking  $O(n + c + st \log st)$  time. The total time is  $O(t[a + s \log n] + (n + c + st \log st))$ . If no new entries appear in  $\mathbf{C}$  the time drops to  $O(t[a + s \log n])$ , and in this case, the time for both methods is the same; both are equally efficient.

A few simplifying assumptions are useful to compare these times. Consider a graph of  $n$  nodes with  $O(n)$  edges, and with a constant bound on the degree of each node. The asymptotic bounds assume a worst-case scenario where  $\mathbf{C}$  has at least some dense rows (thus the  $\log n$  terms). If these are not present, if both  $t$  and  $c$  are  $O(n)$ , and if  $a$  and  $s$  are constants, then the total time with blocking mode becomes  $O(n^2)$ , assuming the pattern of  $\mathbf{C}$  changes at each assignment. This is very high for a sparse graph problem. In contrast, the non-blocking time becomes  $O(n \log n)$  under these same assumptions, which is asymptotically much faster.

The difference in practice can be very dramatic, since  $n$  can be many millions for sparse graphs with  $n$  nodes and  $O(n)$ , which can be handled on a commodity laptop.

The following guidelines should be considered when using `GxB_subassign`, `GrB_assign` and `GrB*_setElement`.

1. A sequence of assignments that does not modify the pattern at all is fast, taking as little as  $\Omega(1)$  time per entry modified. The worst case time complexity is  $O(\log n)$  per entry, assuming they all modify a dense row of `C` with `n` entries, which can occur in practice. It is more common, however, that most rows of `C` have a constant number of entries, independent of `n`. No work is ever left pending when the pattern of `C` does not change.
2. A sequence of assignments that modifies the entries that already exist in the pattern of a matrix, or adds new entries to the pattern (using the same `accum` operator), but does not delete any entries, is fast. The matrix is not completed until the end of the sequence.
3. Similarly, a sequence that modifies existing entries, or deletes them, but does not add new ones, is also fast. This sequence can also repeatedly delete pre-existing entries and then reinstate them and still be fast. The matrix is not completed until the end of the sequence.
4. A sequence that mixes assignments of types (2) and (3) above can be costly, since the matrix may need to be completed after each assignment. The time complexity can become quadratic in the worst case.
5. However, any single assignment takes no more than  $O(a + s \log n + n + c + s \log s)$  time, even including the time for a matrix completion, where `C` is  $n$ -by- $n$  with  $c$  entries and `A` is  $a$ -by- $a$  with  $s$  entries. This time is essentially linear in the size of the matrix `C`, if `A` is relatively small and sparse compared with `C`. In this case,  $n + c$  are the two dominant terms.
6. In general, `GxB_subassign` is faster than `GrB_assign`. If `GrB_REPLACE` is used with `GrB_assign`, the entire matrix `C` must be traversed. This is much slower than `GxB_subassign`, which only needs to examine the `C(I,J)` submatrix. Furthermore, `GrB_assign` must deal with a much larger `Mask` matrix, whereas `GxB_subassign` has a smaller mask. Since

its mask is smaller, `GxB_subassign` takes less time than `GrB_assign` to access the mask.

Submatrix assignment in SuiteSparse:GraphBLAS is extremely efficient, even without considering the advantages of non-blocking mode discussed in Section 12.11. It can be up to 1000x faster than MATLAB R2019b, or even higher depending on the kind of matrix assignment. MATLAB logical indexing (the mask of GraphBLAS) is extremely faster with GraphBLAS as compared in MATLAB R2019b; differences of up to 250,000x have been observed (0.4 seconds in GraphBLAS versus 28 hours in MATLAB).

All of the algorithmic variants of `assign`/`subassign` in SuiteSparse:GraphBLAS are either asymptotically optimal, or to within a log factor of being asymptotically optimal. The methods are also fully parallel. For hypersparse matrices, the term  $n$  in the expressions in the above discussion is dropped, and is replaced with  $h \log h$ , at the worst case, where  $h \ll n$  is the number of non-empty columns of a hypersparse matrix stored by column, or the number of non-empty rows of a hypersparse matrix stored by row. In many methods,  $n$  is replaced with  $h$ , not  $h \log h$ .

## 12.12 GrB\_apply: apply a unary, binary, or index-unary operator

GrB\_apply is the generic name for 92 specific functions:

- GrB\_Vector\_apply and GrB\_Matrix\_apply apply a unary operator to the entries of a matrix (two variants).
- GrB\_\*\_apply\_BinaryOp1st\_\* applies a binary operator where a single scalar is provided as the  $x$  input to the binary operator. There are 30 variants, depending on the type of the scalar: (matrix or vector)  $\times$  (13 built-in types, one for user-defined types, and a version for GrB\_Scalar).
- GrB\_\*\_apply\_BinaryOp2nd\_\* applies a binary operator where a single scalar is provided as the  $y$  input to the binary operator. There are 30 variants, depending on the type of the scalar: (matrix or vector)  $\times$  (13 built-in types, one for user-defined types, and a version for GrB\_Scalar).
- GrB\_\*\_apply\_IndexOp\_\* applies a GrB\_IndexUnaryOp, single scalar is provided as the scalar  $y$  input to the index-unary operator. There are 30 variants, depending on the type of the scalar: (matrix or vector)  $\times$  (13 built-in types, one for user-defined types, and a version for GrB\_Scalar).

The generic name appears in the function prototypes, but the specific function name is used when describing each variation. When discussing features that apply to all versions, the simple name GrB\_apply is used.

### 12.12.1 GrB\_Vector\_apply: apply a unary operator to a vector

```
GrB_Info GrB_apply                // w<mask> = accum (w, op(u))
(
    GrB_Vector w,                  // input/output vector for results
    const GrB_Vector mask,         // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,      // optional accum for z=accum(w,t)
    const GrB_UnaryOp op,          // operator to apply to the entries
    const GrB_Vector u,            // first input: vector u
    const GrB_Descriptor desc      // descriptor for w and mask
) ;
```

GrB\_Vector\_apply applies a unary operator to the entries of a vector, analogous to  $t = \text{op}(u)$  in MATLAB except the operator  $\text{op}$  is only applied

to entries in the pattern of  $\mathbf{u}$ . Implicit values outside the pattern of  $\mathbf{u}$  are not affected. The entries in  $\mathbf{u}$  are typecasted into the **xtype** of the unary operator. The vector  $\mathbf{t}$  has the same type as the **ztype** of the unary operator. The final step is  $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{t}$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices.

### 12.12.2 GrB\_Matrix\_apply: apply a unary operator to a matrix

```
GrB_Info GrB_apply          // C<Mask> = accum (C, op(A)) or op(A')
(
    GrB_Matrix C,           // input/output matrix for results
    const GrB_Matrix Mask,  // optional mask for C, unused if NULL
    const GrB_BinaryOp accum, // optional accum for Z=accum(C,T)
    const GrB_UnaryOp op,   // operator to apply to the entries
    const GrB_Matrix A,     // first input:  matrix A
    const GrB_Descriptor desc // descriptor for C, mask, and A
) ;
```

`GrB_Matrix_apply` applies a unary operator to the entries of a matrix, analogous to  $\mathbf{T} = \text{op}(\mathbf{A})$  in MATLAB except the operator `op` is only applied to entries in the pattern of  $\mathbf{A}$ . Implicit values outside the pattern of  $\mathbf{A}$  are not affected. The input matrix  $\mathbf{A}$  may be transposed first. The entries in  $\mathbf{A}$  are typecasted into the **xtype** of the unary operator. The matrix  $\mathbf{T}$  has the same type as the **ztype** of the unary operator. The final step is  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$ , as described in Section 2.3.

The built-in `GrB_IDENTITY_T` operators (one for each built-in type  $T$ ) are very useful when combined with this function, enabling it to compute  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}$ . This makes `GrB_apply` a direct interface to the accumulator/mask function for both matrices and vectors. The `GrB_IDENTITY_T` operators also provide the fastest stand-alone typecasting methods in Suite-Sparse:GraphBLAS, with all  $13 \times 13 = 169$  methods appearing as individual functions, to typecast between any of the 13 built-in types.

To compute  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{A}$  or  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{A}$  for user-defined types, the user application would need to define an identity operator for the type. Since GraphBLAS cannot detect that it is an identity operator, it must call the operator to make the full copy  $\mathbf{T}=\mathbf{A}$  and apply the operator to each entry of the matrix or vector.

The other GraphBLAS operation that provides a direct interface to the accumulator/mask function is `GrB_transpose`, which does not require an operator to perform this task. As a result, `GrB_transpose` can be used as

an efficient and direct interface to the accumulator/mask function for both built-in and user-defined types. However, it is only available for matrices, not vectors.

### 12.12.3 GrB\_Vector.apply.BinaryOp1st: apply a binary operator to a vector; 1st scalar binding

```
GrB_Info GrB_apply                                // w<mask> = accum (w, op(x,u))
(
    GrB_Vector w,                                  // input/output vector for results
    const GrB_Vector mask,                         // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,                     // optional accum for z=accum(w,t)
    const GrB_BinaryOp op,                        // operator to apply to the entries
    <type> x,                                       // first input: scalar x
    const GrB_Vector u,                           // second input: vector u
    const GrB_Descriptor desc                      // descriptor for w and mask
) ;
```

`GrB_Vector_apply.BinaryOp1st_<type>` applies a binary operator  $z = f(x, y)$  to a vector, where a scalar  $x$  is bound to the first input of the operator. The scalar  $x$  can be a non-opaque C scalar corresponding to a built-in type, a `void *` for user-defined types, or a `GrB_Scalar`. It is otherwise identical to `GrB_Vector_apply`.

The `op` can be any binary operator except that it cannot be a user-defined `GrB_BinaryOp` created by `GxB_BinaryOp_new_IndexOp`. For backward compatibility with prior versions of SuiteSparse:GraphBLAS, built-in index-based binary operators such as `GxB_FIRSTI_INT32` may be used, however. The equivalent index-unity operators are used in their place.

#### 12.12.4 GrB\_Vector\_apply\_BinaryOp2nd: apply a binary operator to a vector; 2nd scalar binding

```
GrB_Info GrB_apply                // w<mask> = accum (w, op(u,y))
(
    GrB_Vector w,                  // input/output vector for results
    const GrB_Vector mask,         // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,      // optional accum for z=accum(w,t)
    const GrB_BinaryOp op,         // operator to apply to the entries
    const GrB_Vector u,            // first input:  vector u
    <type> y,                      // second input: scalar y
    const GrB_Descriptor desc      // descriptor for w and mask
) ;
```

`GrB_Vector_apply_BinaryOp2nd_<type>` applies a binary operator  $z = f(x, y)$  to a vector, where a scalar  $y$  is bound to the second input of the operator. The scalar  $x$  can be a non-opaque C scalar corresponding to a built-in type, a void \* for user-defined types, or a `GrB_Scalar`. It is otherwise identical to `GrB_Vector_apply`.

The `op` can be any binary operator except that it cannot be a user-defined `GrB_BinaryOp` created by `GxB_BinaryOp_new_IndexOp`. For backward compatibility with prior versions of SuiteSparse:GraphBLAS, built-in index-based binary operators such as `GxB_FIRSTI_INT32` may be used, however. The equivalent index-unary operators are used in their place.

#### 12.12.5 GrB\_Vector\_apply\_IndexOp: apply an index-unary operator to a vector

```
GrB_Info GrB_apply                // w<mask> = accum (w, op(u,y))
(
    GrB_Vector w,                  // input/output vector for results
    const GrB_Vector mask,         // optional mask for w, unused if NULL
    const GrB_BinaryOp accum,      // optional accum for z=accum(w,t)
    const GrB_IndexUnaryOp op,     // operator to apply to the entries
    const GrB_Vector u,            // first input:  vector u
    const <type> y,                // second input: scalar y
    const GrB_Descriptor desc      // descriptor for w and mask
) ;
```

`GrB_Vector_apply_IndexOp_<type>` applies an index-unary operator  $z = f(x, i, 0, y)$  to a vector. The scalar  $y$  can be a non-opaque C scalar corresponding to a built-in type, a void \* for user-defined types, or a `GrB_Scalar`. It is otherwise identical to `GrB_Vector_apply`.

### 12.12.6 GrB\_Matrix\_apply\_BinaryOp1st: apply a binary operator to a matrix; 1st scalar binding

```
GrB_Info GrB_apply                // C<M>=accum(C,op(x,A))
(
    GrB_Matrix C,                  // input/output matrix for results
    const GrB_Matrix Mask,         // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,      // optional accum for Z=accum(C,T)
    const GrB_BinaryOp op,        // operator to apply to the entries
    <type> x,                      // first input: scalar x
    const GrB_Matrix A,           // second input: matrix A
    const GrB_Descriptor desc      // descriptor for C, mask, and A
) ;
```

`GrB_Matrix_apply_BinaryOp1st_<type>` applies a binary operator  $z = f(x, y)$  to a matrix, where a scalar  $x$  is bound to the first input of the operator. The scalar  $x$  can be a non-opaque C scalar corresponding to a built-in type, a `void *` for user-defined types, or a `GrB_Scalar`. It is otherwise identical to `GrB_Matrix_apply`.

The `op` can be any binary operator except that it cannot be a user-defined `GrB_BinaryOp` created by `GxB_BinaryOp_new_IndexOp`. For backward compatibility with prior versions of SuiteSparse:GraphBLAS, built-in index-based binary operators such as `GxB_FIRSTI_INT32` may be used, however. The equivalent index-unity operators are used in their place.

### 12.12.7 GrB\_Matrix\_apply\_BinaryOp2nd: apply a binary operator to a matrix; 2nd scalar binding

```
GrB_Info GrB_apply                // C<M>=accum(C,op(A,y))
(
    GrB_Matrix C,                  // input/output matrix for results
    const GrB_Matrix Mask,         // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,      // optional accum for Z=accum(C,T)
    const GrB_BinaryOp op,        // operator to apply to the entries
    const GrB_Matrix A,           // first input: matrix A
    <type> y,                      // second input: scalar y
    const GrB_Descriptor desc      // descriptor for C, mask, and A
) ;
```

`GrB_Matrix_apply_BinaryOp2nd_<type>` applies a binary operator  $z = f(x, y)$  to a matrix, where a scalar  $x$  is bound to the second input of the

operator. The scalar  $y$  can be a non-opaque C scalar corresponding to a built-in type, a `void *` for user-defined types, or a `GrB_Scalar`. It is otherwise identical to `GrB_Matrix_apply`.

The `op` can be any binary operator except that it cannot be a user-defined `GrB_BinaryOp` created by `GxB_BinaryOp_new_IndexOp`. For backward compatibility with prior versions of SuiteSparse:GraphBLAS, built-in index-based binary operators such as `GxB_FIRSTI_INT32` may be used, however. The equivalent index-unary operators are used in their place.

#### 12.12.8 `GrB_Matrix_apply_IndexOp`: apply an index-unary operator to a matrix

```
GrB_Info GrB_apply                                // C<M>=accum(C,op(A,y))
(
    GrB_Matrix C,                                // input/output matrix for results
    const GrB_Matrix Mask,                       // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,                   // optional accum for Z=accum(C,T)
    const GrB_IndexUnaryOp op,                 // operator to apply to the entries
    const GrB_Matrix A,                        // first input:  matrix A
    const <type> y,                             // second input: scalar y
    const GrB_Descriptor desc                  // descriptor for C, mask, and A
) ;
```

`GrB_Matrix_apply_IndexOp_<type>` applies an index-unary operator  $z = f(x, i, j, y)$  to a matrix. The scalar  $y$  can be a non-opaque C scalar corresponding to a built-in type, a `void *` for user-defined types, or a `GrB_Scalar`. It is otherwise identical to `GrB_Matrix_apply`.

## 12.13 GrB\_select: select entries based on an index-unity operator

The `GrB_select` function is the generic name for 30 specific functions, depending on whether it operates on a matrix or vector, and depending on the type of the scalar `y`: (matrix or vector)  $\times$  (13 built-in types, `void *` for user-defined types, and a `GrB_Scalar`). The generic name appears in the function prototypes, but the specific function name is used when describing each variation. When discussing features that apply to both versions, the simple name `GrB_select` is used.

### 12.13.1 GrB\_Vector\_select: select entries from a vector

```
GrB_Info GrB_select          // w<mask> = accum (w, op(u))
(
    GrB_Vector w,             // input/output vector for results
    const GrB_Vector mask,    // optional mask for w, unused if NULL
    const GrB_BinaryOp accum, // optional accum for z=accum(w,t)
    const GrB_IndexUnaryOp op, // operator to apply to the entries
    const GrB_Vector u,       // first input: vector u
    const <type> y,           // second input: scalar y
    const GrB_Descriptor desc  // descriptor for w and mask
) ;
```

`GrB_Vector_select_*` applies a `GrB_IndexUnaryOp` operator to the entries of a vector. If the operator evaluates as `true` for the entry `u(i)`, it is copied to the vector `t`, or not copied if the operator evaluates to `false`. The vector `t` is then written to the result `w` via the mask/accumulator step. This operation operates on vectors just as if they were `m`-by-1 matrices, except that GraphBLAS never transposes a vector via the descriptor. Refer to the next section ([12.13.2](#)) on `GrB_Matrix_select` for more details.

### 12.13.2 GrB\_Matrix\_select: apply a select operator to a matrix

```

GrB_Info GrB_select          // C<M>=accum(C,op(A))
(
    GrB_Matrix C,             // input/output matrix for results
    const GrB_Matrix Mask,    // optional mask for C, unused if NULL
    const GrB_BinaryOp accum, // optional accum for Z=accum(C,T)
    const GrB_IndexUnaryOp op, // operator to apply to the entries
    const GrB_Matrix A,       // first input:  matrix A
    const GrB_Scalar y,       // second input: scalar y
    const GrB_Descriptor desc  // descriptor for C, mask, and A
) ;

```

`GrB_Matrix_select_*` applies a `GrB_IndexUnaryOp` operator to the entries of a matrix. If the operator evaluates as `true` for the entry  $A(i,j)$ , it is copied to the matrix  $T$ , or not copied if the operator evaluates to `false`. The input matrix  $A$  may be transposed first. The entries in  $A$  are typecasted into the `xtype` of the select operator. The final step is  $C\langle M \rangle = C \odot T$ , as described in Section 2.3.

The matrix  $T$  has the same size and type as  $A$  (or the transpose of  $A$  if the input is transposed via the descriptor). The entries of  $T$  are a subset of those of  $A$ . Each entry  $A(i,j)$  of  $A$  is passed to the `op`, as  $z = f(a_{ij}, i, j, y)$ . If  $A$  is transposed first then the operator is applied to entries in the transposed matrix,  $A'$ . If  $z$  is returned as `true`, then the entry is copied into  $T$ , unchanged. If it returns `false`, the entry does not appear in  $T$ .

The action of `GrB_select` with the built-in index-unary operators is described in the table below. The MATLAB analogs are precise for `tril` and `triu`, but shorthand for the other operations. The MATLAB `diag` function returns a column with the diagonal, if  $A$  is a matrix, whereas the matrix  $T$  in `GrB_select` always has the same size as  $A$  (or its transpose if the `GrB_INPO` is set to `GrB_TRAN`). In the MATLAB analog column, `diag` is as if it operates like `GrB_select`, where  $T$  is a matrix.

The following operators may be used on matrices with a user-defined type: `GrB_ROWINDEX_*`, `GrB_COLINDEX_*`, `GrB_DIAGINDEX_*`, `GrB_TRIL`, `GrB_TRIU`, `GrB_DIAG`, `GrB_OFFDIAG`, `GrB_COLLE`, `GrB_COLGT`, `GrB_ROWLE`, and `GrB_ROWGT`.

For floating-point values, comparisons with NaN always return false. The `GrB_VALUE*` operators should not be used with a scalar  $y$  that is equal to NaN. For this case, create a user-defined index-unary operator that performs the test with the ANSI C `isnan` function instead.

GraphBLAS name	MATLAB/Octave analog	description
GrB_ROWINDEX_*	$z=i+y$	select $A(i,j)$ if $i \neq -y$
GrB_COLINDEX_*	$z=j+y$	select $A(i,j)$ if $j \neq -y$
GrB_DIAGINDEX_*	$z=j-(i+y)$	select $A(i,j)$ if $j \neq i+y$
GrB_TRIL	$z=(j \leq (i+y))$	select entries on or below the $y$ th diagonal
GrB_TRIU	$z=(j \geq (i+y))$	select entries on or above the $y$ th diagonal
GrB_DIAG	$z=(j == (i+y))$	select entries on the $y$ th diagonal
GrB_OFFDIAG	$z=(j \neq (i+y))$	select entries not on the $y$ th diagonal
GrB_COLLE	$z=(j \leq y)$	select entries in columns 0 to $y$
GrB_COLGT	$z=(j > y)$	select entries in columns $y+1$ and above
GrB_ROWLE	$z=(i \leq y)$	select entries in rows 0 to $y$
GrB_ROWGT	$z=(i > y)$	select entries in rows $y+1$ and above
GrB_VALUENE_T	$z=(a_{ij} \neq y)$	select $A(i,j)$ if it is not equal to $y$
GrB_VALUEEQ_T	$z=(a_{ij} == y)$	select $A(i,j)$ if it is equal to $y$
GrB_VALUEGT_T	$z=(a_{ij} > y)$	select $A(i,j)$ if it is greater than $y$
GrB_VALUEGE_T	$z=(a_{ij} \geq y)$	select $A(i,j)$ if it is greater than or equal to $y$
GrB_VALUELT_T	$z=(a_{ij} < y)$	select $A(i,j)$ if it is less than $y$
GrB_VALUELE_T	$z=(a_{ij} \leq y)$	select $A(i,j)$ if it is less than or equal to $y$

## 12.14 GrB\_reduce: reduce to a vector or scalar

The generic function name `GrB_reduce` may be used for all specific functions discussed in this section. When the details of a specific function are discussed, the specific name is used for clarity.

### 12.14.1 GrB\_Matrix\_reduce\_Monoid reduce a matrix to a vector

```
GrB_Info GrB_reduce          // w<mask> = accum (w,reduce(A))
(
    GrB_Vector w,             // input/output vector for results
    const GrB_Vector mask,    // optional mask for w, unused if NULL
    const GrB_BinaryOp accum, // optional accum for z=accum(w,t)
    const GrB_Monoid monoid,  // reduce monoid for t=reduce(A)
    const GrB_Matrix A,       // first input: matrix A
    const GrB_Descriptor desc  // descriptor for w, mask, and A
) ;
```

`GrB_Matrix_reduce_Monoid` reduces a matrix to a column vector using a monoid, roughly analogous to  $\mathbf{t} = \text{sum}(\mathbf{A}')$  in MATLAB, in the default case, where  $\mathbf{t}$  is a column vector. By default, the method reduces across the rows to obtain a column vector; use `GrB_TRAN` to reduce down the columns.

The input matrix  $\mathbf{A}$  may be transposed first. Its entries are then typecast into the type of the `reduce` operator or monoid. The reduction is applied to all entries in  $\mathbf{A}(i,:)$  to produce the scalar  $\mathbf{t}(i)$ . This is done without the use of the identity value of the monoid. If the  $i$ th row  $\mathbf{A}(i,:)$  has no entries, then  $\mathbf{t}(i)$  is not an entry in  $\mathbf{t}$  and its value is implicit. If  $\mathbf{A}(i,:)$  has a single entry, then that is the result  $\mathbf{t}(i)$  and `reduce` is not applied at all for the  $i$ th row. Otherwise, multiple entries in row  $\mathbf{A}(i,:)$  are reduced via the `reduce` operator or monoid to obtain a single scalar, the result  $\mathbf{t}(i)$ .

The final step is  $\mathbf{w}\langle\mathbf{m}\rangle = \mathbf{w} \odot \mathbf{t}$ , as described in Section 2.3, except that all the terms are column vectors instead of matrices.

### 12.14.2 GrB\_Vector\_reduce\_<type>: reduce a vector to a scalar

```
GrB_Info GrB_reduce          // c = accum (c, reduce_to_scalar (u))
(
    <type> *c,                // result scalar
    const GrB_BinaryOp accum, // optional accum for c=accum(c,t)
    const GrB_Monoid monoid,  // monoid to do the reduction
    const GrB_Vector u,       // vector to reduce
    const GrB_Descriptor desc  // descriptor (currently unused)
) ;

GrB_Info GrB_reduce          // c = accum (c, reduce_to_scalar (u))
(
    GrB_Scalar c,             // result scalar
    const GrB_BinaryOp accum, // optional accum for c=accum(c,t)
    const GrB_Monoid monoid,  // monoid to do the reduction
    const GrB_Vector u,       // vector to reduce
    const GrB_Descriptor desc  // descriptor (currently unused)
) ;
```

`GrB_Vector_reduce_<type>` reduces a vector to a scalar, analogous to `t = sum (u)` in MATLAB, except that in GraphBLAS any commutative and associative monoid can be used in the reduction.

The scalar `c` can be a pointer C type: `bool`, `int8_t`, ... `float`, `double`, or `void *` for a user-defined type, or a `GrB_Scalar`. If `c` is a `void *` pointer to a user-defined type, the type must be identical to the type of the vector `u`. This cannot be checked by GraphBLAS and thus results are undefined if the types are not the same.

If the vector `u` has no entries, that identity value of the `monoid` is copied into the scalar `t` (unless `c` is a `GrB_Scalar`, in which case `t` is an empty `GrB_Scalar`, with no entry). Otherwise, all of the entries in the vector are reduced to a single scalar using the `monoid`.

The descriptor is unused, but it appears in case it is needed in future versions of the GraphBLAS API. This function has no mask so its accumulator/mask step differs from the other GraphBLAS operations. It does not use the methods described in Section 2.3, but uses the following method instead.

If `accum` is `NULL`, then the scalar `t` is typecast into the type of `c`, and `c = t` is the final result. Otherwise, the scalar `t` is typecast into the `ytype` of the `accum` operator, and the value of `c` (on input) is typecast into the `xtype` of the `accum` operator. Next, the scalar `z = accum (c,t)` is computed, of the `ztype` of the `accum` operator. Finally, `z` is typecast into the final result, `c`.

If `c` is a non-opaque scalar, no error message can be returned by `GrB_error`. If `c` is a `GrB_Scalar`, then `GrB_error(&err,c)` can be used to return an error string, if an error occurs.

### 12.14.3 `GrB_Matrix_reduce_<type>`: reduce a matrix to a scalar

```
GrB_Info GrB_reduce           // c = accum (c, reduce_to_scalar (A))
(
    <type> *c,                 // result scalar
    const GrB_BinaryOp accum,  // optional accum for c=accum(c,t)
    const GrB_Monoid monoid,   // monoid to do the reduction
    const GrB_Matrix A,       // matrix to reduce
    const GrB_Descriptor desc  // descriptor (currently unused)
) ;

GrB_Info GrB_reduce           // c = accum (c, reduce_to_scalar (A))
(
    GrB_Scalar c,             // result scalar
    const GrB_BinaryOp accum,  // optional accum for c=accum(c,t)
    const GrB_Monoid monoid,   // monoid to do the reduction
    const GrB_Matrix A,       // matrix to reduce
    const GrB_Descriptor desc  // descriptor (currently unused)
) ;
```

`GrB_Matrix_reduce_<type>` reduces a matrix `A` to a scalar, roughly analogous to `t = sum (A (:))` in MATLAB. This function is identical to reducing a vector to a scalar, since the positions of the entries in a matrix or vector have no effect on the result. Refer to the reduction to scalar described in the previous Section [12.14.2](#).

## 12.15 GrB\_transpose: transpose a matrix

```
GrB_Info GrB_transpose          // C<Mask> = accum (C, A')
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(C,T)
    const GrB_Matrix A,          // first input:  matrix A
    const GrB_Descriptor desc    // descriptor for C, Mask, and A
) ;
```

`GrB_transpose` transposes a matrix  $A$ , just like the array transpose  $T = A.'$  in MATLAB. The internal result matrix  $T = A'$  (or merely  $T = A$  if  $A$  is transposed via the descriptor) has the same type as  $A$ . The final step is  $C\langle M \rangle = C \odot T$ , as described in Section 2.3, which typecasts  $T$  as needed and applies the mask and accumulator.

To be consistent with the rest of the GraphBLAS API regarding the descriptor, the input matrix  $A$  may be transposed first by setting the `GrB_INP0` setting to `GrB_TRAN`. This results in a double transpose, and thus  $A$  is not transposed is computed.

## 12.16 GrB\_kronecker: Kronecker product

```

GrB_Info GrB_kronecker          // C<Mask> = accum (C, kron(A,B))
(
    GrB_Matrix C,                // input/output matrix for results
    const GrB_Matrix Mask,       // optional mask for C, unused if NULL
    const GrB_BinaryOp accum,    // optional accum for Z=accum(C,T)
    const <operator> op,         // defines '*' for T=kron(A,B)
    const GrB_Matrix A,          // first input:  matrix A
    const GrB_Matrix B,          // second input: matrix B
    const GrB_Descriptor desc    // descriptor for C, Mask, A, and B
) ;

```

`GrB_kronecker` computes the Kronecker product,  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \text{kron}(\mathbf{A}, \mathbf{B})$  where

$$\text{kron}(\mathbf{A}, \mathbf{B}) = \begin{bmatrix} a_{00} \otimes \mathbf{B} & \dots & a_{0,n-1} \otimes \mathbf{B} \\ \vdots & \ddots & \vdots \\ a_{m-1,0} \otimes \mathbf{B} & \dots & a_{m-1,n-1} \otimes \mathbf{B} \end{bmatrix}$$

The  $\otimes$  operator is defined by the `op` parameter. It is applied in an element-wise fashion (like `GrB_eWiseMult`), where the pattern of the submatrix  $a_{ij} \otimes \mathbf{B}$  is the same as the pattern of  $\mathbf{B}$  if  $a_{ij}$  is an entry in the matrix  $\mathbf{A}$ , or empty otherwise. The input matrices  $\mathbf{A}$  and  $\mathbf{B}$  can be of any dimension, and both matrices may be transposed first via the descriptor, `desc`. Entries in  $\mathbf{A}$  and  $\mathbf{B}$  are typecast into the input types of the `op`. The matrix  $\mathbf{T} = \text{kron}(\mathbf{A}, \mathbf{B})$  has the same type as the `ztype` of the binary operator, `op`. The final step is  $\mathbf{C}\langle\mathbf{M}\rangle = \mathbf{C} \odot \mathbf{T}$ , as described in Section 2.3.

The operator `op` may be a `GrB_BinaryOp`, a `GrB_Monoid`, or a `GrB_Semiring`. In the latter case, the multiplicative operator of the semiring is used. The `op` may be a binary operator created by `GxB_BinaryOp_new_IndexOp`.

## 13 Printing GraphBLAS objects

The ten different objects handled by SuiteSparse:GraphBLAS are all opaque, although nearly all of their contents can be extracted via methods such as `GrB_Matrix_extractTuples`, `GrB_Matrix_extractElement`, `GrB_get`, and so on. The GraphBLAS C API has no mechanism for printing all the contents of GraphBLAS objects, but this is helpful for debugging. Ten type-specific methods and two type-generic methods are provided:

<code>GxB_Type_fprint</code>	print and check a <code>GrB_Type</code>
<code>GxB_UnaryOp_fprint</code>	print and check a <code>GrB_UnaryOp</code>
<code>GxB_BinaryOp_fprint</code>	print and check a <code>GrB_BinaryOp</code>
<code>GxB_IndexUnaryOp_fprint</code>	print and check a <code>GrB_IndexUnaryOp</code>
<code>GxB_IndexBinaryOp_fprint</code>	print and check a <code>GxB_IndexBinaryOp</code>
<code>GxB_Monoid_fprint</code>	print and check a <code>GrB_Monoid</code>
<code>GxB_Semiring_fprint</code>	print and check a <code>GrB_Semiring</code>
<code>GxB_Descriptor_fprint</code>	print and check a <code>GrB_Descriptor</code>
<code>GxB_Context_fprint</code>	print and check a <code>GxB_Context</code>
<code>GxB_Matrix_fprint</code>	print and check a <code>GrB_Matrix</code>
<code>GxB_Vector_fprint</code>	print and check a <code>GrB_Vector</code>
<code>GxB_Scalar_fprint</code>	print and check a <code>GrB_Scalar</code>
<code>GxB_fprint</code>	print/check any object to a file
<code>GxB_print</code>	print/check any object to <code>stdout</code>

These methods do not modify the status of any object, and thus they cannot return an error string for use by `GrB_error`.

If a matrix or vector has not been completed, the pending computations are guaranteed to *not* be performed. The reason is simple. It is possible for a bug in the user application (such as accessing memory outside the bounds of an array) to mangle the internal content of a GraphBLAS object, and the `GxB_*print` methods can be helpful tools to track down this bug. If `GxB_*print` attempted to complete any computations prior to printing or checking the contents of the matrix or vector, then further errors could occur, including a segfault.

By contrast, GraphBLAS methods and operations that return values into user-provided arrays or variables might finish pending operations before the return these values, and this would change their state. Since they do not change the state of any object, the `GxB_*print` methods provide a useful method for debugging, and for a quick understanding of what GraphBLAS is computing while developing a user application.

Each of the methods has a parameter of type `GxB_Print_Level` that specifies the amount to print:

```
typedef enum
{
    GxB_SILENT = 0,      // nothing is printed, just check the object
    GxB_SUMMARY = 1,     // print a terse summary
    GxB_SHORT = 2,       // short description, about 30 entries of a matrix
    GxB_COMPLETE = 3,    // print the entire contents of the object
    GxB_SHORT_VERBOSE = 4, // GxB_SHORT but with "%.15g" for doubles
    GxB_COMPLETE_VERBOSE = 5 // GxB_COMPLETE but with "%.15g" for doubles
}
GxB_Print_Level ;
```

The ten type-specific functions include an additional argument, the `name` string. The `name` is printed at the beginning of the display (assuming the print level is not `GxB_SILENT`) so that the object can be more easily identified in the output. For the type-generic methods `GxB_fprint` and `GxB_print`, the `name` string is the variable name of the object itself.

If the file `f` is `NULL`, `stdout` is used. If `name` is `NULL`, it is treated as the empty string. These are not error conditions.

The methods check their input objects carefully and extensively, even when `pr` is equal to `GxB_SILENT`. The following error codes can be returned:

- `GrB_SUCCESS`: object is valid
- `GrB_UNINITIALIZED_OBJECT`: object is not initialized
- `GrB_INVALID_OBJECT`: object is not valid
- `GrB_NULL_POINTER`: object is a `NULL` pointer
- `GrB_INVALID_VALUE`: `fprintf` returned an I/O error.

The content of any GraphBLAS object is opaque, and subject to change. As a result, the exact content and format of what is printed is implementation-dependent, and will change from version to version of SuiteSparse:GraphBLAS. Do not attempt to rely on the exact content or format by trying to parse the resulting output via another program. The intent of these functions is to produce a report of an object for visual inspection. If the user application needs to extract content from a GraphBLAS matrix or vector, use `GrB*_extractTuples` or the import/export methods instead.

GraphBLAS matrices and vectors are zero-based, where indices of an  $n$ -by- $n$  matrix are in the range 0 to  $n - 1$ . However, MATLAB, Octave,

and Julia prefer to print their matrices and vectors as one-based. To enable 1-based printing, use `GrB_set (GrB_GLOBAL, true, GxB_PRINT_1BASED)`. Printing is done as zero-based by default.

### 13.1 GxB\_fprint: Print a GraphBLAS object to a file

```
GrB_Info GxB_fprint          // print and check a GraphBLAS object
(
    GrB_<objecttype> object,  // object to print and check
    int pr,                  // print level (GxB_Print_Level)
    FILE *f                  // file for output
) ;
```

The `GxB_fprint` function prints the contents of any of the ten GraphBLAS objects to the file `f`. If `f` is `NULL`, the results are printed to `stdout`. For example, to print the entire contents of a matrix `A` to the file `f`, use `GxB_fprint (A, GxB_COMPLETE, f)`.

### 13.2 GxB\_print: Print a GraphBLAS object to stdout

```
GrB_Info GxB_print          // print and check a GrB_Vector
(
    GrB_<objecttype> object,  // object to print and check
    int pr,                  // print level (GxB_Print_Level)
) ;
```

`GxB_print` is the same as `GxB_fprint`, except that it prints the contents of the object to `stdout` instead of a file `f`. For example, to print the entire contents of a matrix `A`, use `GxB_print (A, GxB_COMPLETE)`.

### 13.3 GxB\_Type\_fprint: Print a GrB\_Type

```
GrB_Info GxB_Type_fprint    // print and check a GrB_Type
(
    GrB_Type type,           // object to print and check
    const char *name,        // name of the object
    int pr,                  // print level (GxB_Print_Level)
    FILE *f                  // file for output
) ;
```

For example, `GxB_Type_fprint (GrB_BOOL, "boolean type", GxB_COMPLETE, f)` prints the contents of the `GrB_BOOL` object to the file `f`.

### 13.4 GxB\_UnaryOp\_fprint: Print a GrB\_UnaryOp

```
GrB_Info GxB_UnaryOp_fprint      // print and check a GrB_UnaryOp
(
    GrB_UnaryOp unaryop,         // object to print and check
    const char *name,            // name of the object
    int pr,                      // print level (GxB_Print_Level)
    FILE *f                      // file for output
);
```

For example, `GxB_UnaryOp_fprint (GrB_LNOT, "not", GxB_COMPLETE, f)` prints the `GrB_LNOT` unary operator to the file `f`.

### 13.5 GxB\_BinaryOp\_fprint: Print a GrB\_BinaryOp

```
GrB_Info GxB_BinaryOp_fprint     // print and check a GrB_BinaryOp
(
    GrB_BinaryOp binaryop,       // object to print and check
    const char *name,            // name of the object
    int pr,                      // print level (GxB_Print_Level)
    FILE *f                      // file for output
);
```

For example, `GxB_BinaryOp_fprint (GrB_PLUS_FP64, "plus", GxB_COMPLETE, f)` prints the `GrB_PLUS_FP64` binary operator to the file `f`.

### 13.6 GxB\_IndexUnaryOp\_fprint: Print a GrB\_IndexUnaryOp

```
GrB_Info GxB_IndexUnaryOp_fprint // print and check a GrB_IndexUnaryOp
(
    GrB_IndexUnaryOp op,         // object to print and check
    const char *name,            // name of the object
    int pr,                      // print level (GxB_Print_Level)
    FILE *f                      // file for output
);
```

For example, `GrB_IndexUnaryOp_fprint (GrB_TRIL, "tril", GxB_COMPLETE, f)` prints the `GrB_TRIL` index-unary operator to the file `f`.

### 13.7 GxB\_IndexBinaryOp\_fprint: Print a GxB\_IndexBinaryOp

```
GrB_Info GxB_IndexBinaryOp_fprint    // print and check a GxB_IndexBinaryOp
(
    GxB_IndexBinaryOp op,             // object to print and check
    const char *name,                 // name of the object
    int pr,                           // print level (GxB_Print_Level)
    FILE *f                           // file for output
);
```

### 13.8 GxB\_Monoid\_fprint: Print a GrB\_Monoid

```
GrB_Info GxB_Monoid_fprint           // print and check a GrB_Monoid
(
    GrB_Monoid monoid,                // object to print and check
    const char *name,                 // name of the object
    int pr,                           // print level (GxB_Print_Level)
    FILE *f                           // file for output
);
```

For example, `GxB_Monoid_fprint (GxB_PLUS_FP64_MONOID, "plus monoid", GxB_COMPLETE, f)` prints the predefined `GxB_PLUS_FP64_MONOID` (based on the binary operator `GrB_PLUS_FP64`) to the file `f`.

### 13.9 GxB\_Semiring\_fprint: Print a GrB\_Semiring

```
GrB_Info GxB_Semiring_fprint         // print and check a GrB_Semiring
(
    GrB_Semiring semiring,            // object to print and check
    const char *name,                 // name of the object
    int pr,                           // print level (GxB_Print_Level)
    FILE *f                           // file for output
);
```

For example, `GxB_Semiring_fprint (GxB_PLUS_TIMES_FP64, "standard", GxB_COMPLETE, f)` prints the predefined `GxB_PLUS_TIMES_FP64` semiring to the file `f`.

### 13.10 GxB\_Descriptor\_fprint: Print a GrB\_Descriptor

```
GrB_Info GxB_Descriptor_fprint      // print and check a GrB_Descriptor
(
    GrB_Descriptor descriptor,      // object to print and check
    const char *name,              // name of the object
    int pr,                        // print level (GxB_Print_Level)
    FILE *f                        // file for output
);
```

For example, `GxB_Descriptor_fprint (d, "descriptor", GxB_COMPLETE, f)` prints the descriptor `d` to the file `f`.

### 13.11 GxB\_Context\_fprint: Print a GxB\_Context

```
GrB_Info GxB_Context_fprint         // print and check a GxB_Context
(
    GxB_Context Context,           // object to print and check
    const char *name,              // name of the object
    int pr,                        // print level (GxB_Print_Level)
    FILE *f                        // file for output
);
```

This method can be used to print the context created for a user thread, or the contents of the `GxB_CONTEXT_WORLD` object.

### 13.12 GxB\_Matrix\_fprint: Print a GrB\_Matrix

```
GrB_Info GxB_Matrix_fprint          // print and check a GrB_Matrix
(
    GrB_Matrix A,                 // object to print and check
    const char *name,              // name of the object
    int pr,                        // print level (GxB_Print_Level)
    FILE *f                        // file for output
);
```

For example, `GxB_Matrix_fprint (A, "my matrix", GxB_SHORT, f)` prints about 30 entries from the matrix `A` to the file `f`.

### 13.13 GxB\_Vector\_fprint: Print a GrB\_Vector

```
GrB_Info GxB_Vector_fprint      // print and check a GrB_Vector
(
    GrB_Vector v,                // object to print and check
    const char *name,            // name of the object
    int pr,                      // print level (GxB_Print_Level)
    FILE *f                      // file for output
);
```

For example, `GxB_Vector_fprint (v, "my vector", GxB_SHORT, f)` prints about 30 entries from the vector `v` to the file `f`.

### 13.14 GxB\_Scalar\_fprint: Print a GrB\_Scalar

```
GrB_Info GxB_Scalar_fprint      // print and check a GrB_Scalar
(
    GrB_Scalar s,                // object to print and check
    const char *name,            // name of the object
    int pr,                      // print level (GxB_Print_Level)
    FILE *f                      // file for output
);
```

For example, `GxB_Scalar_fprint (s, "my scalar", GxB_SHORT, f)` prints a short description of the scalar `s` to the file `f`.

### 13.15 Performance and portability considerations

Even when the print level is `GxB_SILENT`, these methods extensively check the contents of the objects passed to them, which can take some time. They should be considered debugging tools only, not for final use in production.

The return value of the `GxB_*print` methods can be relied upon, but the output to the file (or `stdout`) can change from version to version. If these methods are eventually added to the GraphBLAS C API Specification, a conforming implementation might never print anything at all, regardless of the `pr` value. This may be essential if the GraphBLAS library is installed in a dedicated device, with no file output, for example.

Some implementations may wish to print nothing at all if the matrix is not yet completed, or just an indication that the matrix has pending operations and cannot be printed, when non-blocking mode is employed. In this case, use `GrB_Matrix_wait`, `GrB_Vector_wait`, or `GxB_Scalar_wait` to finish all

pending computations first. If a matrix or vector has pending operations, SuiteSparse:GraphBLAS prints a list of the *pending tuples*, which are the entries not yet inserted into the primary data structure. It can also print out entries that remain in the data structure but are awaiting deletion; these are called *zombies* in the output report.

Most of the rest of the report is self-explanatory.

## 14 Matrix and Vector iterators

The `GxB_Iterator` is an object that allows user applications to iterate over the entries of a matrix or vector, one entry at a time. Iteration can be done in a linear manner (analogous to reading a file one entry at a time, from start to finish), or in a random-access pattern (analogous to the `fseek` method for repositioning the access to file to a different position).

Multiple iterators can be used on a single matrix or vector, even in parallel by multiple user threads. While a matrix or vector is being used with an iterator, the matrix or vector must not be modified. Doing so will lead to undefined results.

Since accessing a matrix or vector via an iterator requires many calls to the iterator methods, they must be very fast. Error checking is skipped, except for the methods that create, attach, or free an iterator. Methods that advance an iterator or that access values or indices from a matrix or vector do not return error conditions. Instead, they have well-defined preconditions that must be met (and which should be checked by the user application). If those preconditions are not met, results are undefined.

The iterator methods are implemented in SuiteSparse:GraphBLAS as both macros (via `#define`) and as functions of the same name that appear in the compiled `libgraphblas.so` library. This requires that the opaque contents of the iterator object be defined in `GraphBLAS.h` itself. The user application must not access these contents directly, but can only do so safely via the iterator methods provided by SuiteSparse:GraphBLAS.

The iterator object can be used in one of four sets of methods, for four different access patterns:

1. *row iterator*: iterates across the rows of a matrix, and then within each row to access the entries in a given row. Accessing all the entries of a matrix using a row iterator requires an outer loop (for the rows) and an inner loop (for the entries in each row). A matrix can be accessed via a row iterator only if its format (determined by `GrB_get (A, &fmt, GrB_STORAGE_ORIENTATION_HINT)`) is by-row (that is, `GrB_ROWMAJOR`). See Section 10.
2. *column iterator*: iterates across the columns of a matrix, and then within each column to access the entries in a given column. Accessing all the entries of a matrix using a column iterator requires an outer loop

(for the columns) and an inner loop (for the entries in each column). A matrix can be accessed via a column iterator only if its format (determined by `GrB_get (A, &fmt, GrB_STORAGE_ORIENTATION_HINT)`) is by-column (that is, `GrB_COLMAJOR`). See Section 10.

3. *entry iterator*: iterates across the entries of a matrix. Accessing all the entries of a matrix using an entry iterator requires just a single loop. Any matrix can be accessed with an entry iterator.
4. *vector iterator*: iterates across the entries of a vector. Accessing all the entries of a vector using a vector iterator requires just a single loop. Any vector can be accessed with a vector iterator.

## 14.1 Creating and destroying an iterator

The process for using an iterator starts with the creation of an iterator, with `GxB_Iterator_new`. This method creates an `iterator` object but does not *attach* it to any specific matrix or vector:

```
GxB_Iterator iterator ;
GxB_Iterator_new (&iterator) ;
```

When finished, the `iterator` is freed with either of these methods:

```
GrB_free (&iterator) ;
GxB_Iterator_free (&iterator) ;
```

## 14.2 Attaching an iterator to a matrix or vector

This new `iterator` object can be *attached* to any matrix or vector, and used as a row, column, or entry iterator for any matrix, or as an iterator for any vector. The `iterator` can be used in any of these methods before it is freed, but with just one access method at a time.

Once it is created, the `iterator` must be attached to a matrix or vector. This process also selects the method by which the `iterator` will be used for a matrix. Each of the four `GxB_*Iterator_attach` methods returns a `GrB_Info` result.

1. *row iterator*:

```
GrB_Info info = GxB_rowIterator_attach (iterator, A, desc) ;
```

2. *column iterator*:

```
GrB_Info info = GxB_colIterator_attach (iterator, A, desc) ;
```

3. *entry iterator*:

```
GrB_Info info = GxB_Matrix_Iterator_attach (iterator, A, desc) ;
```

4. *vector iterator*:

```
GrB_Info info = GxB_Vector_Iterator_attach (iterator, v, desc) ;
```

On input to `GxB_*Iterator_attach`, the `iterator` must already exist, having been created by `GxB_Iterator_new`. If the `iterator` is already attached to a matrix or vector, it is detached and then attached to the given matrix `A` or vector `v`.

The return values for row/column methods are:

- `GrB_SUCCESS`: if the `iterator` is successfully attached to the matrix `A`.
- `GrB_NULL_POINTER`: if the `iterator` or `A` are `NULL`.
- `GrB_INVALID_OBJECT`: if the matrix `A` is invalid.
- `GrB_NOT_IMPLEMENTED`: if the matrix `A` cannot be iterated in the requested access method (row iterators require the matrix to be held by-row, and column iterators require the matrix to be held by-column).
- `GrB_OUT_OF_MEMORY`: if the method runs out of memory.

The other two methods (entry iterator for matrices, or the vector iterator) return the same error codes, except that they do not return `GrB_NOT_IMPLEMENTED`.

### 14.3 Seeking to an arbitrary position

Attaching the `iterator` to a matrix or vector does not define a specific position for the `iterator`. To use the `iterator`, a single call to the corresponding *seek* method is required. These `GxB*_Iterator_*seek*` methods may also be used later on to change the position of the iterator arbitrarily.

1. *row iterator*:

```

GrB_Info info = GxB_rowIterator_seekRow (iterator, row) ;
GrB_Index kount = GxB_rowIterator_kount (iterator) ;
GrB_Info info = GxB_rowIterator_kseek (iterator, k) ;

```

These methods move a row iterator to a specific row, defined in one of two ways: (1) the row index itself (in range 0 to `nrows-1`), or (2) by specifying `k`, which moves the iterator to the *k*th *explicit* row (in the range 0 to `kount-1`). For sparse, bitmap, or full matrices, these two methods are identical. For hypersparse matrices, not all rows are present in the data structure; these *implicit* rows are skipped and not included in the `kount`. Implicit rows contain no entries. The `GxB_rowIterator_kount` method returns the `kount` of the matrix, where `kount` is equal to `nrows` for sparse, bitmap, and matrices, and `kount`  $\leq$  `nrows` for hypersparse matrices. All three methods listed above can be used for any row iterator.

The `GxB_rowIterator_*seek*` methods return `GrB_SUCCESS` if the iterator has been moved to a row that contains at least one entry, `GrB_NO_VALUE` if the row has no entries, or `GxB_EXHAUSTED` if the row is out of bounds (`row`  $\geq$  `nrows` or if `k`  $\geq$  `kount`). None of these return conditions are errors; they are all informational.

For sparse, bitmap, and full matrices, `GxB_rowIterator_seekRow` always moves to the given row. For hypersparse matrices, if the requested row is implicit, the iterator is moved to the first explicit row following it. If no such row exists, the iterator is exhausted and `GxB_EXHAUSTED` is returned. The `GxB_rowIterator_kseek` method always moves to the *k*th explicit row, for any matrix. Use `GxB_rowIterator_getRowIndex`, described below, to determine the row index of the current position.

Precondition: on input, the `iterator` must have been successfully attached to a matrix via a prior call to `GxB_rowIterator_attach`. Results are undefined if this precondition is not met.

## 2. *column iterator:*

```

GrB_Info info = GxB_colIterator_seekCol (iterator, col) ;
GrB_Index kount = GxB_colIterator_kount (iterator) ;
GrB_Info info = GxB_colIterator_kseek (iterator, k) ;

```

These methods move a column iterator to a specific column, defined in one of two ways: (1) the column index itself (in range 0 to `ncols-1`), or

(2) by specifying **k**, which moves the iterator to the **k**th *explicit* column (in the range 0 to **kount**-1). For sparse, bitmap, or full matrices, these two methods are identical. For hypersparse matrices, not all columns are present in the data structure; these *implicit* columns are skipped and not included in the **kount**. Implicit columns contain no entries. The **GxB\_colIterator\_kount** method returns the **kount** of the matrix, where **kount** is equal to **ncols** for sparse, bitmap, and matrices, and **kount**  $\leq$  **ncols** for hypersparse matrices. All three methods listed above can be used for any column iterator.

The **GxB\_colIterator\_\*seek\*** methods return **GrB\_SUCCESS** if the iterator has been moved to a column that contains at least one entry, **GrB\_NO\_VALUE** if the column has no entries, or **GxB\_EXHAUSTED** if the column is out of bounds (**col**  $\geq$  **ncols** or **k**  $\geq$  **kount**). None of these return conditions are errors; they are all informational.

For sparse, bitmap, and full matrices, **GxB\_colIterator\_seekCol** always moves to the given column. For hypersparse matrices, if the requested column is implicit, the iterator is moved to the first explicit column following it. If no such column exists, the iterator is exhausted and **GxB\_EXHAUSTED** is returned. The **GxB\_colIterator\_kseek** method always moves to the **k**th explicit column, for any matrix. Use **GxB\_colIterator\_getColIndex**, described below, to determine the column index of the current position.

Precondition: on input, the **iterator** must have been successfully attached to a matrix via a prior call to **GxB\_colIterator\_attach**. Results are undefined if this precondition is not met.

### 3. *entry iterator*:

```
GrB_Info info = GxB_Matrix_Iterator_seek (iterator, p) ;
GrB_Index pmax = GxB_Matrix_Iterator_getpmax (iterator) ;
GrB_Index p = GxB_Matrix_Iterator_getp (iterator);
```

The **GxB\_Matrix\_Iterator\_seek** method moves the **iterator** to the given position **p**, which is in the range 0 to **pmax**-1, where the value of **pmax** is obtained from **GxB\_Matrix\_Iterator\_getpmax**. For sparse, hypersparse, and full matrices, **pmax** is the same as **nvals** returned by **GrB\_Matrix\_nvals**. For bitmap matrices, **pmax** is equal to **nrows\*ncols**.

If  $p \geq p_{\max}$ , the iterator is exhausted and `GxB_EXHAUSTED` is returned. Otherwise, `GrB_SUCCESS` is returned.

All entries in the matrix are given an ordinal position,  $p$ . Seeking to position  $p$  will either move the `iterator` to that particular position, or to the next higher position containing an entry if there is entry at position  $p$ . The latter case only occurs for bitmap matrices. Use `GxB_Matrix_Iterator_getp` to determine the current position of the iterator.

Precondition: on input, the `iterator` must have been successfully attached to a matrix via a prior call to `GxB_Matrix_Iterator_attach`. Results are undefined if this precondition is not met.

4. *vector iterator*:

```
GrB_Info info = GxB_Vector_Iterator_seek (iterator, p) ;
GrB_Index pmax = GxB_Vector_Iterator_getpmax (iterator) ;
GrB_Index p = GxB_Vector_Iterator_getp (iterator);
```

The `GxB_Vector_Iterator_seek` method is identical to the entry iterator of a matrix, but applied to a `GrB_Vector` instead.

Precondition: on input, the `iterator` must have been successfully attached to a vector via a prior call to `GxB_Vector_Iterator_attach`. Results are undefined if this precondition is not met.

## 14.4 Advancing to the next position

For best performance, the *seek* methods described above should be used with care, since some of them require  $O(\log n)$  time. The fastest method for changing the position of the iterator is the corresponding *next* method, described below for each iterator:

1. *row iterator*: To move to the next row.

```
GrB_Info info = GxB_rowIterator_nextRow (iterator) ;
```

The row iterator is a 2-dimensional iterator, requiring an outer loop and an inner loop. The outer loop iterates over the rows of the matrix, using `GxB_rowIterator_nextRow` to move to the next row. If the matrix

is hypersparse, the next row is always an explicit row; implicit rows are skipped. The return conditions are identical to `GxB_rowIterator_seekRow`.

Preconditions: on input, the row iterator must already be attached to a matrix via a prior call to `GxB_rowIterator_attach`, and the `iterator` must be at a specific row, via a prior call to `GxB_rowIterator_*seek*` or `GxB_rowIterator_nextRow`. Results are undefined if these conditions are not met.

2. *row iterator*: To move to the next entry within a row.

```
GrB_Info info = GxB_rowIterator_nextCol (iterator) ;
```

The row iterator is moved to the next entry in the current row. The method returns `GrB_NO_VALUE` if the end of the row is reached. The iterator does not move to the next row in this case. The method returns `GrB_SUCCESS` if the iterator has been moved to a specific entry in the current row.

Preconditions: the same as `GxB_rowIterator_nextRow`.

3. *column iterator*: To move to the next column

```
GrB_Info info = GxB_colIterator_nextCol (iterator) ;
```

The column iterator is a 2-dimensional iterator, requiring an outer loop and an inner loop. The outer loop iterates over the columns of the matrix, using `GxB_colIterator_nextCol` to move to the next column. If the matrix is hypersparse, the next column is always an explicit column; implicit columns are skipped. The return conditions are identical to `GxB_colIterator_seekCol`.

Preconditions: on input, the column iterator must already be attached to a matrix via a prior call to `GxB_colIterator_attach`, and the `iterator` must be at a specific column, via a prior call to `GxB_colIterator_*seek*` or `GxB_colIterator_nextCol`. Results are undefined if these conditions are not met.

4. *column iterator*: To move to the next entry within a column.

```
GrB_Info info = GxB_colIterator_nextRow (iterator) ;
```

The column iterator is moved to the next entry in the current column. The method returns `GrB_NO_VALUE` if the end of the column is reached. The iterator does not move to the next column in this case. The method returns `GrB_SUCCESS` if the iterator has been moved to a specific entry in the current column.

Preconditions: the same as `GxB_colIterator_nextCol`.

5. *entry iterator*: To move to the next entry.

```
GrB_Info info = GxB_Matrix_Iterator_next (iterator) ;
```

This method moves an iterator to the next entry of a matrix. It returns `GrB_SUCCESS` if the iterator is at an entry that exists in the matrix, or `GrB_EXHAUSTED` otherwise.

Preconditions: on input, the entry iterator must be already attached to a matrix via `GxB_Matrix_Iterator_attach`, and the position of the iterator must also have been defined by a prior call to `GxB_Matrix_Iterator_seek` or `GxB_Matrix_Iterator_next`. Results are undefined if these conditions are not met.

6. *vector iterator*: To move to the next entry.

```
GrB_Info info = GxB_Vector_Iterator_next (iterator) ;
```

This method moves an iterator to the next entry of a vector. It returns `GrB_SUCCESS` if the iterator is at an entry that exists in the vector, or `GrB_EXHAUSTED` otherwise.

Preconditions: on input, the iterator must be already attached to a vector via `GxB_Vector_Iterator_attach`, and the position of the iterator must also have been defined by a prior call to `GxB_Vector_Iterator_seek` or `GxB_Vector_Iterator_next`. Results are undefined if these conditions are not met.

## 14.5 Accessing the indices of the current entry

Once the iterator is attached to a matrix or vector, and is placed in position at an entry in the matrix or vector, the indices and value of this entry can be obtained. The methods for accessing the value of the entry are described in Section 14.6. Accessing the indices is performed with four different sets of methods, depending on which access pattern is in use, described below:

1. *row iterator*: To get the current row index.

```
GrB_Index i = GxB_rowIterator_getRowIndex (iterator) ;
```

The method returns `nrows(A)` if the iterator is exhausted, or the current row index `i` otherwise. There need not be any entry in the current row. Zero is returned if the iterator is attached to the matrix but `GxB_rowIterator_*seek*` has not been called, but this does not mean the iterator is positioned at row zero.

Preconditions: on input, the iterator must be already successfully attached to matrix as a row iterator via `GxB_rowIterator_attach`. Results are undefined if this condition is not met.

2. *row iterator*: To get the current column index.

```
GrB_Index j = GxB_rowIterator_getColIndex (iterator) ;
```

Preconditions: on input, the iterator must be already successfully attached to matrix as a row iterator via `GxB_rowIterator_attach`, and in addition, the row iterator must be positioned at a valid entry present in the matrix. That is, the last call to `GxB_rowIterator_*seek*` or `GxB_rowIterator_*next*`, must have returned `GrB_SUCCESS`. Results are undefined if these conditions are not met.

3. *column iterator*: To get the current column index.

```
GrB_Index j = GxB_colIterator_getColIndex (iterator) ;
```

The method returns `ncols(A)` if the iterator is exhausted, or the current column index `j` otherwise. There need not be any entry in the current column. Zero is returned if the iterator is attached to the matrix but `GxB_colIterator_*seek*` has not been called, but this does not mean the iterator is positioned at column zero.

Precondition: on input, the iterator must be already successfully attached to matrix as a column iterator via `GxB_colIterator_attach`. Results are undefined if this condition is not met.

4. *column iterator*: To get the current row index.

```
GrB_Index i = GxB_colIterator_getRowIndex (iterator) ;
```

Preconditions: on input, the iterator must be already successfully attached to matrix as a column iterator via `GxB_colIterator_attach`, and in addition, the column iterator must be positioned at a valid entry present in the matrix. That is, the last call to `GxB_colIterator_*seek*` or `GxB_colIterator_*next*`, must have returned `GrB_SUCCESS`. Results are undefined if these conditions are not met.

5. *entry iterator*: To get the current row and column index.

```
GrB_Index i, j ;
GxB_Matrix_Iterator_getIndex (iterator, &i, &j) ;
```

Returns the row and column index of the current entry.

Preconditions: on input, the entry iterator must be already attached to a matrix via `GxB_Matrix_Iterator_attach`, and the position of the iterator must also have been defined by a prior call to `GxB_Matrix_Iterator_seek` or `GxB_Matrix_Iterator_next`, with a return value of `GrB_SUCCESS`. Results are undefined if these conditions are not met.

6. *vector iterator*: To get the current index.

```
GrB_Index i = GxB_Vector_Iterator_getIndex (iterator) ;
```

Returns the index of the current entry.

Preconditions: on input, the entry iterator must be already attached to a matrix via `GxB_Vector_Iterator_attach`, and the position of the iterator must also have been defined by a prior call to `GxB_Vector_Iterator_seek` or `GxB_Vector_Iterator_next`, with a return value of `GrB_SUCCESS`. Results are undefined if these conditions are not met.

## 14.6 Accessing the value of the current entry

So far, all methods that create or use an iterator have been split into four sets of methods, for the row, column, or entry iterators attached to a matrix, or for a vector iterator. Accessing the value is different. All four iterators use the same set of methods to access the value of their current entry. These methods return the value of the current entry at the position determined by the iterator. The return value can of course be typecasted using standard C syntax once the value is returned to the caller.

Preconditions: on input, the prior call to `GxB_*Iterator_*seek*`, or `GxB_*Iterator_*next*` must have returned `GrB_SUCCESS`, indicating that the iterator is at a valid current entry for either a matrix or vector. No typecasting is permitted, in the sense that the method name must match the type of the matrix or vector. Results are undefined if these conditions are not met.

```
// for built-in types:
bool      value = GxB_Iterator_get_BOOL (iterator) ;
int8_t    value = GxB_Iterator_get_INT8 (iterator) ;
int16_t   value = GxB_Iterator_get_INT16 (iterator) ;
int32_t   value = GxB_Iterator_get_INT32 (iterator) ;
int64_t   value = GxB_Iterator_get_INT64 (iterator) ;
uint8_t   value = GxB_Iterator_get_UINT8 (iterator) ;
uint16_t  value = GxB_Iterator_get_UINT16 (iterator) ;
uint32_t  value = GxB_Iterator_get_UINT32 (iterator) ;
uint64_t  value = GxB_Iterator_get_UINT64 (iterator) ;
float     value = GxB_Iterator_get_FP32 (iterator) ;
double    value = GxB_Iterator_get_FP64 (iterator) ;
GxB_FC32_t value = GxB_Iterator_get_FC32 (iterator) ;
GxB_FC64_t value = GxB_Iterator_get_FC64 (iterator) ;

// for user-defined types:
<type> value ;
GxB_Iterator_get_UDT (iterator, (void *) &value) ;
```

## 14.7 Example: row iterator for a matrix

The following example uses a row iterator to access all of the entries in a matrix `A` of type `GrB_FP64`. Note the inner and outer loops. The outer loop iterates over all rows of the matrix. The inner loop iterates over all entries in the row `i`. This access pattern requires the matrix to be held by-row, but otherwise it works for any matrix. If the matrix is held by-column, then use the column iterator methods instead.

```
// create an iterator
GxB_Iterator iterator ;
GxB_Iterator_new (&iterator) ;
// attach it to the matrix A, known to be type GrB_FP64
GrB_Info info = GxB_rowIterator_attach (iterator, A, NULL) ;
if (info < 0) { handle the failure ... }
// seek to A(0,:)
info = GxB_rowIterator_seekRow (iterator, 0) ;
while (info != GxB_EXHAUSTED)
{
    // iterate over entries in A(i,:)
    GrB_Index i = GxB_rowIterator_getRowIndex (iterator) ;
    while (info == GrB_SUCCESS)
    {
        // get the entry A(i,j)
        GrB_Index j = GxB_rowIterator_getColIndex (iterator) ;
        double aij = GxB_Iterator_get_FP64 (iterator) ;
        // move to the next entry in A(i,:)
        info = GxB_rowIterator_nextCol (iterator) ;
    }
    // move to the next row, A(i+1,:), or a subsequent one if i+1 is implicit
    info = GxB_rowIterator_nextRow (iterator) ;
}
GxB_free (&iterator) ;
```

## 14.8 Example: column iterator for a matrix

The column iterator is analogous to the row iterator.

The following example uses a column iterator to access all of the entries in a matrix **A** of type **GrB\_FP64**. The outer loop iterates over all columns of the matrix. The inner loop iterates over all entries in the column **j**. This access pattern requires the matrix to be held by-column, but otherwise it works for any matrix. If the matrix is held by-row, then use the row iterator methods instead.

```
// create an iterator
GxB_Iterator iterator ;
GxB_Iterator_new (&iterator) ;
// attach it to the matrix A, known to be type GrB_FP64
GrB_Info info = GxB_colIterator_attach (iterator, A, NULL) ;
// seek to A(:,0)
info = GxB_colIterator_seekCol (iterator, 0) ;
while (info != GxB_EXHAUSTED)
{
    // iterate over entries in A(:,j)
    GrB_Index j = GxB_colIterator_getColIndex (iterator) ;
    while (info == GrB_SUCCESS)
    {
        // get the entry A(i,j)
        GrB_Index i = GxB_colIterator_getRowIndex (iterator) ;
        double  aij = GxB_Iterator_get_FP64 (iterator) ;
        // move to the next entry in A(:,j)
        info = GxB_colIterator_nextRow (iterator) ;
    }
    // move to the next column, A(:,j+1), or a subsequent one if j+1 is implicit
    info = GxB_colIterator_nextCol (iterator) ;
}
GrB_free (&iterator) ;
```

## 14.9 Example: entry iterator for a matrix

The entry iterator allows for a simpler access pattern, with a single loop, but using a row or column iterator is faster. The method works for any matrix.

```
// create an iterator
GxB_Iterator iterator ;
GxB_Iterator_new (&iterator) ;
// attach it to the matrix A, known to be type GrB_FP64
GrB_Info info = GxB_Matrix_Iterator_attach (iterator, A, NULL) ;
if (info < 0) { handle the failure ... }
// seek to the first entry
info = GxB_Matrix_Iterator_seek (iterator, 0) ;
while (info != GxB_EXHAUSTED)
{
    // get the entry A(i,j)
    GrB_Index i, j ;
    GxB_Matrix_Iterator_getIndex (iterator, &i, &j) ;
    double aij = GxB_Iterator_get_FP64 (iterator) ;
    // move to the next entry in A
    info = GxB_Matrix_Iterator_next (iterator) ;
}
GrB_free (&iterator) ;
```

## 14.10 Example: vector iterator

A vector iterator is used much like an entry iterator for a matrix.

```
// create an iterator
GxB_Iterator iterator ;
GxB_Iterator_new (&iterator) ;
// attach it to the vector v, known to be type GrB_FP64
GrB_Info info = GxB_Vector_Iterator_attach (iterator, v, NULL) ;
if (info < 0) { handle the failure ... }
// seek to the first entry
info = GxB_Vector_Iterator_seek (iterator, 0) ;
while (info != GxB_EXHAUSTED)
{
    // get the entry v(i)
    GrB_Index i = GxB_Vector_Iterator_getIndex (iterator) ;
    double vi = GxB_Iterator_get_FP64 (iterator) ;
    // move to the next entry in v
    info = GxB_Vector_Iterator_next (iterator) ;
}
GrB_free (&iterator) ;
```

## 14.11 Performance

I have benchmarked the performance of the row and column iterators to compute  $y=0$  and then  $y+=A*x$  where  $y$  is a dense vector and  $A$  is a sparse matrix, using a single thread. The row and column iterators are very fast, sometimes only 1% slower than calling `GrB_m xv` to compute the same thing (also assuming a single thread), for large problems. For sparse matrices that average just 1 or 2 entries per row, the row iterator can be about 30% slower than `GrB_m xv`, likely because of the slightly higher complexity of moving from one row to the next using these methods.

It is possible to split up the problem for multiple user threads, each with its own iterator. Given the low overhead of the row and column iterator for a single thread, this should be very fast. Care must be taken to ensure a good load balance. Simply splitting up the rows of a matrix and giving the same number of rows to each user thread can result in imbalanced work. This is handled internally in `GrB_*` methods, but enabling parallelism when using iterators is the responsibility of the user application.

The entry iterators are easier to use but harder to implement. The methods must internally fuse both inner and outer loops so that the user application can use a single loop. As a result, the computation  $y+=A*x$  can be up to 4x slower (about 2x typical) than when using `GrB_m xv` with a single thread.

To obtain the best performance possible, many of the iterator methods are implemented as macros in `GraphBLAS.h`. Using macros is the default, giving typical C and C++ applications access to the fastest methods possible.

To ensure access to these methods when not using the macros, these methods are also defined as regular functions that appear in the compiled `libgraphblas.so` library with the same name as the macros. Applications that cannot use the macro versions can `#undef` the macros after the `#include <GraphBLAS.h>` statement, and then they would access the regular compiled functions in `libgraphblas.so`. This non-macro approach is not the default, and the iterator methods may be slightly slower.

## 15 Iso-Valued Matrices and Vectors

The GraphBLAS C API states that the entries in all `GrB_Matrix` and `GrB_Vector` objects have a numerical value, with either a built-in or user-defined type. Representing an unweighted graph requires a value to be placed on each edge, typically  $a_{ij} = 1$ . Adding a structure-only data type would not mix well with the rest of GraphBLAS, where all operators, monoids, and semirings need to operate on a value, of some data type. And yet unweighted graphs are very important in graph algorithms.

The solution is simple, and exploiting it in SuiteSparse:GraphBLAS requires nearly no extensions to the GraphBLAS C API. SuiteSparse:GraphBLAS can often detect when the user application is creating a matrix or vector where all entries in the sparsity pattern take on the same numerical value.

For example,  $\mathbf{C}\langle\mathbf{C}\rangle = 1$ , when the mask is structural, sets all entries in  $\mathbf{C}$  to the value 1. SuiteSparse:GraphBLAS detects this, and performs this assignment in  $O(1)$  time. It stores a single copy of this “iso-value” and sets an internal flag in the opaque data structure for  $\mathbf{C}$ , which states that all entries in the pattern of  $\mathbf{C}$  are equal to 1. This saves both time and memory and allows for the efficient representation of sparse adjacency matrices of unweighted graphs, yet does not change the C API. To the user application, it still appears that  $\mathbf{C}$  has `nvals(C)` entries, all equal to 1.

Creating and operating on iso-valued matrices (or just *iso matrices* for short) is significantly faster than creating matrices with different data values. A matrix that is iso requires only  $O(1)$  space for its numerical values. The sparse and hypersparse formats require an additional  $O(n+e)$  or  $O(e)$  integer space to hold the pattern of an  $n$ -by- $n$  matrix  $\mathbf{C}$ , respectively, and a matrix  $\mathbf{C}$  in bitmap format requires  $O(n^2)$  space for the bitmap. A full matrix requires no integer storage, so a matrix that is both iso and full requires only  $O(1)$  space, regardless of its dimension.

The sections below describe the methods that can be used to create iso matrices and vectors. Let  $a$ ,  $b$ , and  $c$  denote the iso values of  $\mathbf{A}$ ,  $\mathbf{B}$ , and  $\mathbf{C}$ , respectively.

### 15.1 Using iso matrices and vectors in a graph algorithm

There are two primary useful ways to use iso-valued matrices and vectors: (1) as iso sparse/hypersparse adjacency matrices for unweighted graphs, and

(2) as iso full matrices or vectors used with operations that do not need to access all of the content of the iso full matrix or vector.

In the first use case, simply create a `GrB_Matrix` with values that are all the same (those in the sparsity pattern). The `GxB_Matrix_build_Scalar` method can be used for this, since it guarantees that the time and work spent on the numerical part of the array is only  $O(1)$ . The method still must spend  $O(e)$  or  $O(e \log e)$  time on the integer arrays that represent the sparsity pattern, but the reduction in time and work on the numerical part of the matrix will improve performance.

The use of `GxB_Matrix_build_Scalar` is optional. Matrices can also be constructed with `GrB*` methods. In particular, `GrB_Matrix_build_*` can be used. It first builds a non-iso matrix and then checks if all of the values are the same, after assembling any duplicate entries. This does not save time or memory for the construction of the matrix itself, but it will lead to savings in time and memory later on, when the matrix is used.

To ensure a matrix `C` is iso-valued, simply use `GrB_assign` to compute `C<C,struct>=1`, or assign whatever value of scalar you wish. It is essential to use a structural mask. Otherwise, it is not clear that all entries in `C` will be assigned the same value. The following code takes  $O(1)$  time, and it resets the size of the numerical part of the `C` matrix to be  $O(1)$  in size:

```
bool scalar = true ;
GrB_Matrix_assign (C, C, NULL, scalar, GrB_ALL, nrows, GrB_ALL, ncols,
    GrB_DESC_S) ;
```

The MATLAB/Octave analog of the code above is `C=spones(C)`.

The second case for where iso matrices and vectors are useful is to use them with operations that do not necessarily access all of their content. Suppose you have a matrix `A` of arbitrarily large dimension (say `n`-by-`n` where `n=2^60`, of type `GrB_FP64`). A matrix this large can be represented by SuiteSparse:GraphBLAS, but only in a hypersparse form.

Now, suppose you wish to compute the maximum value in each row, reducing the matrix to a vector. This can be done with `GrB_reduce`:

```
GrB_Vector_new (&v, GrB_FP64, n) ;
GrB_reduce (v, NULL, GrB_MAX_MONOID_FP64, A, NULL) ;
```

It can also be done with `GrB_m xv`, by creating an iso full vector `x`. The creation of `x` takes  $O(1)$  time and memory, and the `GrB_m xv` computation takes  $O(e)$  time (with modest assumptions; if `A` needs to be transposed the time would be  $O(e \log e)$ ).

```

GrB_Vector_new (&v, GrB_FP64, n) ;
GrB_Vector_new (&x, GrB_FP64, n) ;
GrB_assign (x, NULL, NULL, 1, GrB_ALL, n, NULL) ;
GrB_m xv (v, NULL, NULL, GrB_MAX_FIRST_SEMIRING_FP64, A, x, NULL) ;

```

The above computations are identical in SuiteSparse:GraphBLAS. Internally, `GrB_reduce` creates `x` and calls `GrB_m xv`. Using `GrB_m xm` directly gives the user application additional flexibility in creating new computations that exploit the multiplicative operator in the semiring. `GrB_reduce` always uses the `FIRST` operator in its semiring, but any other binary operator can be used instead when using `GrB_m xv`.

## 15.2 Iso matrices from matrix multiplication

Consider `GrB_m xm`, `GrB_m xv`, and `GrB_v xm`, and let  $C=A*B$ , where no mask is present, or  $C<M>=A*B$  where `C` is initially empty. If `C` is not initially empty, then these rules apply to a temporary matrix  $T<M>=A*B$ , which is initially empty and is then assigned to `C` via  $C<M>=T$ .

The iso property of `C` is determined with the following rules, where the first rule that fits defines the property and value of `C`.

- If the semiring includes a index-based multiplicative operator (`GxB_FIRSTI`, `GrB_SECONDI`, and related operators), then `C` is never iso.
- Define an *iso-monoid* as a built-in monoid with the property that reducing a set of  $n > 1$  identical values  $x$  returns the same value  $x$ . These are the `MIN` `MAX` `LOR` `LAND` `BOR` `BAND` and `ANY` monoids. All other monoids are not iso monoids: `PLUS`, `TIMES`, `LXNOR`, `EQ`, `BXOR`, `BXNOR`, and all user-defined monoids. Currently, there is no mechanism for telling SuiteSparse:GraphBLAS that a user-defined monoid is an iso-monoid.
- If the multiplicative op is `PAIR` (same as `ONEB`), and the monoid is an iso-monoid, or the `EQ` or `TIMES` monoids, then `C` is iso with a value of 1.
- If both `B` and the monoid are iso, and the multiplicative op is `SECOND` or `ANY`, then `C` is iso with a value of  $b$ .
- If both `A` and the monoid are iso, and the multiplicative op is `FIRST` or `ANY`, then `C` is iso with a value of  $a$ .

- If  $A$ ,  $B$ , and the monoid are all iso, then  $C$  is iso, with a value  $c = f(a, b)$ , where  $f$  is any multiplicative op (including user-defined, which assumes that a user-defined  $f$  has no side effects).
- If  $A$  and  $B$  are both iso and full (all entries present, regardless of the format of the matrices), then  $C$  is iso and full. Its iso value is computed in  $O(\log(n))$  time, via a reduction of  $n$  copies of the value  $t = f(a, b)$  to a scalar. The storage required to represent  $C$  is just  $O(1)$ , regardless of its dimension. Technically, the **PLUS** monoid could be computed as  $c = nt$  in  $O(1)$  time, but the log-time reduction works for any monoid, including user-defined ones.
- Otherwise,  $C$  is not iso.

### 15.3 Iso matrices from **eWiseMult** and **kronecker**

Consider **GrB\_eWiseMult**. Let  $C=A.*B$ , or  $C<M>=A.*B$  with any mask and where  $C$  is initially empty, where  $.*$  denotes a binary operator  $f(x, y)$  applied with **eWiseMult**. These rules also apply to **GrB\_kronecker**.

- If the operator is index-based (**GxB\_FIRSTI** and related) then  $C$  is not iso.
- If the op is **PAIR** (same as **ONEB**), then  $C$  is iso with  $c = 1$ .
- If  $B$  is iso and the op is **SECOND** or **ANY**, then  $C$  is iso with  $c = b$ .
- If  $A$  is iso and the op is **FIRST** or **ANY**, then  $C$  is iso with  $c = a$ .
- If both  $A$  and  $B$  are iso, then  $C$  is iso with  $c = f(a, b)$ .
- Otherwise,  $C$  is not iso.

### 15.4 Iso matrices from **eWiseAdd**

Consider **GrB\_eWiseAdd**, and also the accumulator phase of  $C<M>+=T$  when an accumulator operator is present. Let  $C=A+B$ , or  $C<M>=A+B$  with any mask and where  $C$  is initially empty.

- If both  $A$  and  $B$  are full (all entries present), then the rules for **eWiseMult** in Section 15.3 are used instead.

- If the operator is index-based (`GxB_FIRSTI` and related) then `C` is not iso.
- If  $a$  and  $b$  differ (when typecasted to the type of `C`), then `C` is not iso.
- If  $c = f(a, b) = a = b$  holds, then `C` is iso, where  $f(a, b)$  is the operator.
- Otherwise, `C` is not iso.

## 15.5 Iso matrices from `eWiseUnion`

`GxB_eWiseUnion` is very similar to `GrB_eWiseAdd`, but the rules for when the result is iso-valued are very different.

- If both `A` and `B` are full (all entries present), then the rules for `eWiseMult` in Section 15.3 are used instead.
- If the operator is index-based (`GxB_FIRSTI` and related) then `C` is not iso.
- If the op is `PAIR` (same as `ONEB`), then `C` is iso with  $c = 1$ .
- If `B` is iso and the op is `SECOND` or `ANY`, and the input scalar `beta` matches  $b$  (the iso-value of `B`), then `C` is iso with  $c = b$ .
- If `A` is iso and the op is `FIRST` or `ANY`, and the input scalar `alpha` matches  $a$  (the iso-value of `A`), then `C` is iso with  $c = a$ .
- If both `A` and `B` are iso, and  $f(a, b) = f(\alpha, b) = f(a, \beta)$ , then `C` is iso with  $c = f(a, b)$ .
- Otherwise, `C` is not iso.

## 15.6 Reducing iso matrices to a scalar or vector

If `A` is iso with  $e$  entries, reducing it to a scalar takes  $O(\log(e))$  time, regardless of the monoid used to reduce the matrix to a scalar. Reducing `A` to a vector `c` is the same as the matrix-vector multiply  $c = A * x$  or  $c = A' * x$ , depending on the descriptor, where `x` is an iso full vector (refer to Section 15.2).

## 15.7 Iso matrices from apply

Let  $C=f(A)$  denote the application of a unary operator  $f$ , and let  $C=f(A,s)$  and  $C=f(s,A)$  denote the application of a binary operator with  $s$  a scalar.

- If the operator is index-based (`GxB_POSITION*`, `GxB_FIRSTI`, and related) then  $C$  is not iso.
- If the operator is `ONE` or `PAIR` (same as `ONEB`), then  $C$  iso with  $c = 1$ .
- If the operator is `FIRST` or `ANY` with  $C=f(s,A)$ , then  $C$  iso with  $c = s$ .
- If the operator is `SECOND` or `ANY` with  $C=f(A,s)$ , then  $C$  iso with  $c = s$ .
- If  $A$  is iso then  $C$  is iso, with the following value of  $c$ :
  - If the op is `IDENTITY`, then  $c = a$ .
  - If the op is unary with  $C=f(A)$ , then  $c = f(a)$ .
  - If the op is binary with  $C=f(s,A)$ , then  $c = f(s,a)$ .
  - If the op is binary with  $C=f(A,s)$ , then  $c = f(a,s)$ .
- Otherwise,  $C$  is not iso.

## 15.8 Iso matrices from select

Let  $C=\text{select}(A)$  denote the application of a `GrB_IndexUnaryOp` operator in `GrB_select`.

- If  $A$  is iso, then  $C$  is iso with  $c = a$ .
- If the operator is any `GrB_VALUE*_BOOL` operator, with no typecasting, and the test is true only for a single boolean value, then  $C$  is iso.
- If the operator is `GrB_VALUEEQ_*`, with no typecasting, then  $C$  is iso, with  $c = t$  where  $t$  is the value of the scalar  $y$ .
- If the operator is `GrB_VALUELE_UINT*`, with no typecasting, and the scalar  $y$  is zero, then  $C$  is iso with  $c = 0$ .
- Otherwise,  $C$  is not iso.

## 15.9 Iso matrices from assign and subassign

These rules are somewhat complex. Consider the assignment  $C\langle M\rangle(I,J)=\dots$  with `GrB_assign`. Internally, this assignment is converted into  $C(I,J)\langle M(I,J)\rangle=\dots$  and then `GxB_subassign` is used. Thus, all of the rules below assume the form  $C(I,J)\langle M\rangle=\dots$  where  $M$  has the same size as the submatrix  $C(I,J)$ .

### 15.9.1 Assignment with no accumulator operator

If no accumulator operator is present, the following rules are used.

- For matrix assignment,  $A$  must be iso. For scalar assignment, the single scalar is implicitly expanded into an iso matrix  $A$  of the right size. If these rules do not hold,  $C$  is not iso.
- If  $A$  is not iso, or if  $C$  is not iso on input, then  $C$  is not iso on output.
- If  $C$  is iso or empty on input, and  $A$  is iso (or scalar assignment is begin performed) and the iso values  $c$  and  $a$  (or the scalar  $s$ ) match, then the following forms of assignment result in an iso matrix  $C$  on output:

- $C(I,J) = \text{scalar}$
- $C(I,J)\langle M\rangle = \text{scalar}$
- $C(I,J)\langle !M\rangle = \text{scalar}$
- $C(I,J)\langle M,\text{replace}\rangle = \text{scalar}$
- $C(I,J)\langle !M,\text{replace}\rangle = \text{scalar}$
- $C(I,J) = A$
- $C(I,J)\langle M\rangle = A$
- $C(I,J)\langle !M\rangle = A$
- $C(I,J)\langle M,\text{replace}\rangle = A$
- $C(I,J)\langle !M,\text{replace}\rangle = A$

- For these forms of assignment,  $C$  is always iso on output, regardless of its iso property on input:
  - $C = \text{scalar}$

- $C\langle M, \text{struct} \rangle = \text{scalar}$ ;  $C$  empty on input.
- $C\langle C, \text{struct} \rangle = \text{scalar}$
- For these forms of assignment,  $C$  is always iso on output if  $A$  is iso:
  - $C = A$
  - $C\langle M, \text{str} \rangle = A$ ;  $C$  empty on input.

### 15.9.2 Assignment with an accumulator operator

If an accumulator operator is present, the following rules are used. Index-based operators (`GxB_FIRSTI` and related) cannot be used as accumulator operators, so these rules do not consider that case.

- For matrix assignment,  $A$  must be iso. For scalar assignment, the single scalar is implicitly expanded into an iso matrix  $A$  of the right size. If these rules do not hold,  $C$  is not iso.
- For these forms of assignment  $C$  is iso if  $C$  is empty on input, or if  $c = c + a$  for the where  $a$  is the iso value of  $A$  or the value of the scalar for scalar assignment.
  - $C(I, J) += \text{scalar}$
  - $C(I, J)\langle M \rangle += \text{scalar}$
  - $C(I, J)\langle !M \rangle += \text{scalar}$
  - $C(I, J)\langle M, \text{replace} \rangle += \text{scalar}$
  - $C(I, J)\langle !M, \text{replace} \rangle += \text{scalar}$
  - $C(I, J)\langle M, \text{replace} \rangle += A$
  - $C(I, J)\langle !M, \text{replace} \rangle += A$
  - $C(I, J) += A$
  - $C(I, J)\langle M \rangle += A$
  - $C(I, J)\langle !M \rangle += A$
  - $C += A$

## 15.10 Iso matrices from build methods

`GxB_Matrix_build_Scalar` and `GxB_Vector_build_Scalar` always construct an iso matrix/vector.

`GrB_Matrix_build` and `GrB_Vector_build` can also construct iso matrices and vectors. A non-iso matrix/vector is constructed first, and then the entries are checked to see if they are all equal. The resulting iso-valued matrix/vector will be efficient to use and will use less memory than a non-iso matrix/vector. However, constructing an iso matrix/vector with `GrB_Matrix_build` and `GrB_Vector_build` will take more time and memory than constructing the matrix/vector with `GxB_Matrix_build_Scalar` or `GxB_Vector_build_Scalar`.

## 15.11 Iso matrices from other methods

- For `GrB_Matrix_dup` and `GrB_Vector_dup`, the output matrix/vector has the same iso property as the input matrix/vector.
- `GrB_*_setElement_*` preserves the iso property of the matrix/vector it modifies, if the input scalar is equal to the iso value of the matrix/vector. If the matrix or vector has no entries, the first call to `setElement` makes it iso. This allows a sequence of `setElement` calls with the same scalar value to create an entire iso matrix or vector, if starting from an empty matrix or vector.
- `GxB_Matrix_concat` constructs an iso matrix as its result if all input tiles are either empty or iso.
- `GxB_Matrix_split` constructs its output tiles as iso if its input matrix is iso.
- `GxB_Matrix_diag` and `GrB_Matrix_diag` construct an iso matrix if its input vector is iso.
- `GxB_Vector_diag` constructs an iso vector if its input matrix is iso.
- `GrB_*extract` constructs an iso matrix/vector if its input matrix/vector is iso.
- `GrB_transpose` constructs an iso matrix if its input is iso.
- The `GxB_Container` methods preserve the iso property of their matrices/vectors.

## 15.12 Iso matrices not exploited

There are many cases where an matrix may have the iso property but it is not detected by SuiteSparse:GraphBLAS. For example, if  $A$  is non-iso,  $C=A(I,J)$  from `GrB_extract` may be iso, if all entries in the extracted submatrix have the same value. Future versions of SuiteSparse:GraphBLAS may extend the rules described in this section to detect these cases.

## 16 Performance

Getting the best performance out of an algorithm that relies on GraphBLAS can depend on many factors. This section describes some of the possible performance pitfalls you can hit when using SuiteSparse:GraphBLAS, and how to avoid them (or at least know when you’ve encountered them).

### 16.1 The burble is your friend

Turn on the burble with `GrB_set (GrB_GLOBAL, true, GxB_BURBLE)`. You will get a single line of output from each (significant) call to GraphBLAS. The burble output can help you detect when you are likely using sub-optimal methods, as described in the next sections. When the JIT is in use the burble reports when a JIT kernel is run (which is quick), loaded for the first time (which takes a small amount of time), and when a JIT kernels is compiled (which can take a few tenths of a second or more). The compiler command is printed in full. If you encounter a compiler error, you can cut-and-paste the compiler command while outside of your application to help track down the compiler error.

### 16.2 Data types and typecasting: use the JIT

If the JIT is disabled, avoid mixing data types and relying on typecasting as much as possible. SuiteSparse:GraphBLAS has a set of highly-tuned kernels for each data type, and many operators and semirings, but there are too many combinations to generate ahead of time. If typecasting is required, or if SuiteSparse:GraphBLAS does not have a kernel for the specific operator or semiring, the word **generic** will appear in the burble. The generic methods rely on function pointers for each operation on every scalar, so they are slow. Enabling the JIT avoids this problem, since GraphBLAS can then compile kernel specific to the types used.

Without the JIT, the only time that typecasting is fast is when computing  $C=A$  via `GrB_assign` or `GrB_apply`, where the data types of  $C$  and  $A$  can differ. In this case, one of  $13^2 = 169$  kernels are called, each of which performs the specific typecasting requested, without relying on function pointers.

### 16.3 Matrix data structures: sparse, hypersparse, bitmap, or full

SuiteSparse:GraphBLAS tries to automatically determine the best data structure for your matrices and vectors, selecting between sparse, hypersparse, bitmap, and full formats. By default, all 4 formats can be used. A matrix typically starts out hypersparse when it is created by `GrB_Matrix_new`, and then changes during its lifetime, possibly taking on all four different formats at different times. This can be modified via `GrB_set`. For example, this line of code:

```
GrB_set (A, GxB_SPARSE + GxB_BITMAP, GxB_SPARSITY_CONTROL) ;
```

tells SuiteSparse that the matrix `A` can be held in either sparse or bitmap format (at its discretion), but not hypersparse or full. The bitmap format will be used if the matrix has enough entries, or sparse otherwise. Sometimes this selection is best controlled by the user algorithm, so a single format can be requested:

```
GrB_set (A, GxB_SPARSE, GxB_SPARSITY_CONTROL) ;
```

This ensures that SuiteSparse will primarily use the sparse format. This is still just a hint, however. The data structure is opaque and SuiteSparse is free to choose otherwise. In particular, if you insist on using only the `GxB_FULL` format, then that format is used when all entries are present. However, if the matrix is not actually full with all entries present, then the bitmap format is used instead. The full format does not preserve the sparsity structure in this case. Any GraphBLAS library must preserve the proper structure, per the C Specification. This is critical in a graph algorithm, since an edge  $(i, j)$  of weight zero, say, is not the same as no edge  $(i, j)$  at all.

### 16.4 Matrix formats: by row or by column, or using the transpose of a matrix

By default, SuiteSparse uses a simple rule: all matrices are held by row, unless they consist of a single column, in which case they are held by column. All vectors are treated as if they are  $n$ -by-1 matrices with a single column. Changing formats from row-oriented to column-oriented can have

significant performance implications, so SuiteSparse never tries to outguess the application. It just uses this simple rule.

However, there are cases where changing the format can greatly improve performance. There are two ways to handle this, which in the end are equivalent in the SuiteSparse internals. You can change the format (row to column oriented, or visa versa), or work with the explicit transpose of a matrix in the same storage orientation.

There are cases where SuiteSparse must explicitly transpose an input matrix, or the output matrix, in order to perform a computation. For example, if all matrices are held in row-oriented fashion, SuiteSparse does not have a method for computing  $C=A'*B$ , where  $A$  is transposed. Thus, SuiteSparse either computes a temporary transpose of its input matrix  $AT=A'$  and then  $C=AT*B$ , or it swaps the computations, performing  $C=(B'*A)'$ , which requires an explicit transpose of  $BT=B$ , and a transpose of the final result to obtain  $C$ .

These temporary transposes are costly to compute, taking time and memory. They are not kept, but are discarded when the method returns to the user application. If you see the term `transpose` in the burble output, and if you need to perform this computation many times, try constructing your own explicit transpose, say  $AT=A'$ , via `GrB_transpose`, or create a copy of  $A$  but held in another orientation via `GrB_set`. For example, assuming the default matrix format is by-row, and that  $A$  is m-by-n of type `GrB_FP32`:

```
// method 1: AT = A'
GrB_Matrix_new (AT, GrB_FP32, n, m) ;
GrB_transpose (AT, NULL, NULL, A, NULL) ;

// method 2: A2 = A but held by column instead of by row
// note: doing the set before the assign is faster than the reverse
GrB_Matrix_new (A2, GrB_FP32, m, n) ;
GrB_set (A2, GrB_COLMAJOR, GrB_STORAGE_ORIENTATION_HINT) ;
GrB_assign (A2, NULL, NULL, A, GrB_ALL, m, GrB_ALL, n, NULL) ;
```

Internally, the data structure for  $AT$  and  $A2$  are nearly identical (that is, the tranpose of  $A$  held in row format is the same as  $A$  held in column format). Using either of them in subsequent calls to GraphBLAS will allow SuiteSparse to avoid computing an explicit transpose. The two matrices  $AT$  and  $A2$  do differ in one very significant way: their dimensions are different, and they behave differement mathematically. Computing  $C=A'*B$  using these matrices would differ:

```

// method 1: C=A'*B using AT
GrB_mxm (C, NULL, NULL, semiring, AT, B, NULL) ;

// method 2: C=A'*B using A2
GrB_mxm (C, NULL, NULL, semiring, A2, B, GrB_DESC_T0) ;

```

The first method computes  $C=AT*B$ . The second method computes  $C=A2'*B$ , but the result of both computations is the same, and internally the same kernels will be used.

## 16.5 Push/pull optimization

Closely related to the discussion above on when to use a matrix or its transpose is the exploitation of “push/pull” direction optimization. In linear algebraic terms, this is simply deciding whether to multiply by the matrix or its transpose. Examples can be seen in the BFS and Betweenness-Centrality methods of LAGraph. Here is the BFS kernel:

```

int sparsity = do_push ? GxB_SPARSE : GxB_BITMAP ;
GrB_set (q, sparsity, GxB_SPARSITY_CONTROL) ;
if (do_push)
{
    // q'!\pi} = q'*A
    GrB_vxm (q, pi, NULL, semiring, q, A, GrB_DESC_RSC) ;
}
else
{
    // q!\pi} = AT*q
    GrB_mxv (q, pi, NULL, semiring, AT, q, GrB_DESC_RSC) ;
}

```

The call to `GrB_set` is optional, since SuiteSparse will likely already determine that a bitmap format will work best when the frontier `q` has many entries, which is also when the pull step is fastest. The push step relies on a sparse vector times sparse matrix method originally due to Gustavson. The output is computed as a set union of all rows  $A(i, :)$  where  $q(i)$  is present on input. This set union is very fast when `q` is very sparse. The pull step relies on a sequence of dot product computations, one per possible entry in the output `q`, and it uses the matrix `AT` which is a row-oriented copy of the explicit transpose of the adjacency matrix `A`.

Mathematically, the results of the two methods are identical, but internally, the data format of the input matrices is very different (using `A` held

by row, or  $A^T$  held by row which is the same as a copy of  $A$  that is held by column), and the algorithms used are very different.

## 16.6 Computing with full matrices and vectors

Sometimes the best approach to getting the highest performance is to use dense vectors, and occasionally dense matrices are tall-and-thin or short-and-fat. Packages such as Julia, Octave, or MATLAB, when dealing with the conventional plus-times semirings, assume that multiplying a sparse matrix  $A$  times a dense vector  $x$ ,  $y=A*x$ , will result in a dense vector  $y$ . This is not always the case, however. GraphBLAS must always return a result that respects the sparsity structure of the output matrix or vector. If the  $i$ th row of  $A$  has no entries then  $y(i)$  must not appear as an entry in the vector  $y$ , so it cannot be held as a full vector. As a result, the following computation can be slower than it could be:

```
GrB_mxv (y, NULL, NULL, semiring, A, x, NULL) ;
```

SuiteSparse must do extra work to compute the sparsity of this vector  $y$ , but if this is not needed, and  $y$  can be padded with zeros (or the identity value of the monoid, to be precise), a faster method can be used, by relying on the accumulator. Instead of computing  $y=A*x$ , set all entries of  $y$  to zero first, and then compute  $y+=A*x$  where the accumulator operator and type matches the monoid of the semiring. SuiteSparse has special kernels for this case; you can see them in the burble as  $F+=S*F$  for example.

```
// y = 0
GrB_assign (y, NULL, NULL, 0, GrB_ALL, n, NULL) ;
// y += A*x
GrB_mxv (y, NULL, GrB_PLUS_FP32, GrB_PLUS_TIMES_SEMIRING_FP32, A, x, NULL) ;
```

You can see this computation in the LAGraph PageRank method, where all entries of  $r$  are set to the `teleport` scalar first.

```
for (iters = 0 ; iters < itermax && rdiff > tol ; iters++)
{
    // swap t and r ; now t is the old score
    GrB_Vector temp = t ; t = r ; r = temp ;
    // w = t ./ d
    GrB_eWiseMult (w, NULL, NULL, GrB_DIV_FP32, t, d, NULL) ;
    // r = teleport
```

```

    GrB_assign (r, NULL, NULL, teleport, GrB_ALL, n, NULL) ;
    // r += A'*w
    GrB_mvx (r, NULL, GrB_PLUS_FP32, LAGraph_plus_second_fp32, AT, w, NULL) ;
    // t -= r
    GrB_assign (t, NULL, GrB_MINUS_FP32, r, GrB_ALL, n, NULL) ;
    // t = abs (t)
    GrB_apply (t, NULL, NULL, GrB_ABS_FP32, t, NULL) ;
    // rdiff = sum (t)
    GrB_reduce (&rdiff, NULL, GrB_PLUS_MONOID_FP32, t, NULL) ;
}

```

SuiteSparse exploits the iso-valued property of the scalar-to-vector assignment of `y=0`, or `r=teleport`, and performs these assignments in  $O(1)$  time and space. Because the `r` vector start out as full on input to `GrB_mvx`, and because there is an accumulator with no mask, no entries in the input/output vector `r` will be deleted, even if `A` has empty rows. The call to `GrB_mvx` exploits this, and is able to use a fast kernel for this computation. SuiteSparse does not need to compute the sparsity pattern of the vector `r`.

## 16.7 Iso-valued matrices and vectors

Using iso-valued matrices and vectors is always faster than using matrices and vectors whose entries can have different values. Iso-valued matrices are very important in graph algorithms. For example, an unweighted graph is best represented as an iso-valued sparse matrix, and unweighted graphs are very common. The burble output, `GxB_print`, or `GrB_get` can all be used to report whether or not your matrix or vector is iso-valued.

Sometimes a matrix or vector may have values that are all the same, but SuiteSparse hasn't detected this. If this occurs, you can force a matrix or vector to be iso-valued by assigning a single scalar to all its entries.

```

// C<s(C)> = 3.14159
GrB_assign (C, C, NULL, 3.14159, GrB_ALL, m, GrB_ALL, n, GrB_DESC_S) ;

```

The matrix `C` is used as its own mask. The descriptor is essential here, telling the mask to be used in a structural sense, without regard to the values of the entries in the mask. This assignment sets all entries that already exist in `C` to be equal to a single value, 3.14159. The sparsity structure of `C` does not change. Of course, any scalar can be used; the value 1 is common for unweighted graphs. SuiteSparse:GraphBLAS performs the above assignment

in  $O(1)$  time and space, independent of the dimension of  $\mathbb{C}$  or the number of entries in  $\mathbf{c}$ .

## 16.8 User-defined types and operators: use the JIT

If the JIT is disabled, these will be slow. With the JIT enabled, data types and operators are just as fast as built-in types and operators. A CUDA JIT for the GPU is in progress, collaboration with Joe Eaton and Corey Nolet. A SYCL/OpenCL JIT is under consideration, but work has not yet been started.

## 16.9 About NUMA systems

I have tested this package extensively on multicore single-socket systems, but have not yet optimized it for multi-socket systems with a NUMA architecture. That will be done in a future release. If you publish benchmarks with this package, please state the SuiteSparse:GraphBLAS version, and a caveat if appropriate. If you see significant performance issues when going from a single-socket to multi-socket system, I would like to hear from you so I can look into it.

## 17 Examples

Several examples of how to use GraphBLAS are listed below. They all appear in the **Demo** folder of SuiteSparse:GraphBLAS. Programs in the **Demo** folder are meant as simple examples; for the fastest methods, see LAGraph (Section 17.1).

1. creating a random matrix
2. creating a finite-element matrix
3. reading a matrix from a file
4. complex numbers as a user-defined type
5. matrix import/export

Additional examples appear in the newly created LAGraph project, currently in progress.

### 17.1 LAGraph

The LAGraph project is a community-wide effort to create graph algorithms based on GraphBLAS (any implementation of the API, not just SuiteSparse:GraphBLAS). Some of the algorithms and utilities in LAGraph are listed in the table below. Many additional algorithms are planned. Refer to <https://github.com/GraphBLAS/LAGraph> for a current list of algorithms. All functions in the **Demo/** folder in SuiteSparse:GraphBLAS will eventually be translated into algorithms or utilities for LAGraph, and then removed from GraphBLAS/Demo.

To use LAGraph with SuiteSparse:GraphBLAS, place the two folders **LAGraph** and **GraphBLAS** in the same parent directory. This allows the **cmake** script in LAGraph to find the copy of GraphBLAS. Alternatively, the GraphBLAS source could be placed anywhere, as long as **sudo make install** is performed.

### 17.2 Creating a random matrix

The **random\_matrix** function in the **Demo** folder generates a random matrix with a specified dimension and number of entries, either symmetric or unsymmetric, and with or without self-edges (diagonal entries in the matrix).

It relies on `simple_rand*` functions in the Demo folder to provide a portable random number generator that creates the same sequence on any computer and operating system.

`random_matrix` can use one of two methods: `GrB_Matrix_setElement` and `GrB_Matrix_build`. The former method is very simple to use:

```
GrB_Matrix_new (&A, GrB_FP64, nrows, ncols) ;
for (int64_t k = 0 ; k < ntuples ; k++)
{
    GrB_Index i = simple_rand_i ( ) % nrows ;
    GrB_Index j = simple_rand_i ( ) % ncols ;
    if (no_self_edges && (i == j)) continue ;
    double x = simple_rand_x ( ) ;
    // A (i,j) = x
    GrB_Matrix_setElement (A, x, i, j) ;
    if (make_symmetric)
    {
        // A (j,i) = x
        GrB_Matrix_setElement (A, x, j, i) ;
    }
}
```

The above code can generate a million-by-million sparse `double` matrix with 200 million entries in 66 seconds (6 seconds of which is the time to generate the random `i`, `j`, and `x`), including the time to finish all pending computations. The user application does not need to create a list of all the tuples, nor does it need to know how many entries will appear in the matrix. It just starts from an empty matrix and adds them one at a time in arbitrary order. GraphBLAS handles the rest. This method is not feasible in MATLAB.

The next method uses `GrB_Matrix_build`. It is more complex to use than `setElement` since it requires the user application to allocate and fill the tuple lists, and it requires knowledge of how many entries will appear in the matrix, or at least a good upper bound, before the matrix is constructed. It is slightly faster, creating the same matrix in 60 seconds, 51 seconds of which is spent in `GrB_Matrix_build`.

```
GrB_Index *I, *J ;
double *X ;
int64_t s = ((make_symmetric) ? 2 : 1) * nedges + 1 ;
I = malloc (s * sizeof (GrB_Index)) ;
J = malloc (s * sizeof (GrB_Index)) ;
```

```

X = malloc (s * sizeof (double  )) ;
if (I == NULL || J == NULL || X == NULL)
{
    // out of memory
    if (I != NULL) free (I) ;
    if (J != NULL) free (J) ;
    if (X != NULL) free (X) ;
    return (GrB_OUT_OF_MEMORY) ;
}
int64_t ntuples = 0 ;
for (int64_t k = 0 ; k < nedges ; k++)
{
    GrB_Index i = simple_rand_i ( ) % nrows ;
    GrB_Index j = simple_rand_i ( ) % ncols ;
    if (no_self_edges && (i == j)) continue ;
    double x = simple_rand_x ( ) ;
    // A (i,j) = x
    I [ntuples] = i ;
    J [ntuples] = j ;
    X [ntuples] = x ;
    ntuples++ ;
    if (make_symmetric)
    {
        // A (j,i) = x
        I [ntuples] = j ;
        J [ntuples] = i ;
        X [ntuples] = x ;
        ntuples++ ;
    }
}
GrB_Matrix_build (A, I, J, X, ntuples, GrB_SECOND_FP64) ;

```

The equivalent `sprandsym` function in MATLAB takes 150 seconds, but `sprandsym` uses a much higher-quality random number generator to create the tuples `[I,J,X]`. Considering just the time for `sparse(I,J,X,n,n)` in `sprandsym` (equivalent to `GrB_Matrix_build`), the time is 70 seconds. That is, each of these three methods, `setElement` and `build` in SuiteSparse:GraphBLAS, and `sparse` in MATLAB, are equally fast.

### 17.3 Creating a finite-element matrix

Suppose a finite-element matrix is being constructed, with  $k=40,000$  finite-element matrices, each of size  $8\text{-by-}8$ . The following operations (in pseudo-

MATLAB notation) are very efficient in SuiteSparse:GraphBLAS.

```
A = sparse (m,n) ; % create an empty n-by-n sparse GraphBLAS matrix
for i = 1:k
    construct a 8-by-8 sparse or dense finite-element F
    I and J define where the matrix F is to be added:
    I = a list of 8 row indices
    J = a list of 8 column indices
    % using GrB_assign, with the 'plus' accum operator:
    A (I,J) = A (I,J) + F
end
```

If this were done in MATLAB or in GraphBLAS with blocking mode enabled, the computations would be extremely slow. A far better approach is to construct a list of tuples `[I,J,X]` and to use `sparse(I,J,X,n,n)`. This is identical to creating the same list of tuples in GraphBLAS and using the `GrB_Matrix_build`, which is equally fast.

In SuiteSparse:GraphBLAS, the performance of both methods is essentially identical, and roughly as fast as `sparse` in MATLAB. Inside SuiteSparse:GraphBLAS, `GrB_assign` is doing the same thing. When performing `A(I,J)=A(I,J)+F`, if it finds that it cannot quickly insert an update into the `A` matrix, it creates a list of pending tuples to be assembled later on. When the matrix is ready for use in a subsequent GraphBLAS operation (one that normally cannot use a matrix with pending computations), the tuples are assembled all at once via `GrB_Matrix_build`.

GraphBLAS operations on other matrices have no effect on when the pending updates of a matrix are completed. Thus, any GraphBLAS method or operation can be used to construct the `F` matrix in the example above, without affecting when the pending updates to `A` are completed.

The MATLAB `wathen.m` script is part of Higham's `gallery` of matrices [Hig02]. It creates a finite-element matrix with random coefficients for a 2D mesh of size `nx`-by-`ny`, a matrix formulation by Wathen [Wat87]. The pattern of the matrix is fixed; just the values are randomized. The GraphBLAS equivalent can use either `GrB_Matrix_build`, or `GrB_assign`. Both methods have good performance. The `GrB_Matrix_build` version below is about 15% to 20% faster than the MATLAB `wathen.m` function, regardless of the problem size. It uses the identical algorithm as `wathen.m`.

```
int64_t ntriplets = nx*ny*64 ;
I = malloc (ntriplets * sizeof (int64_t)) ;
```

```

J = malloc (ntriplets * sizeof (int64_t)) ;
X = malloc (ntriplets * sizeof (double )) ;
if (I == NULL || J == NULL || X == NULL)
{
    FREE_ALL ;
    return (GrB_OUT_OF_MEMORY) ;
}
ntriplets = 0 ;
for (int j = 1 ; j <= ny ; j++)
{
    for (int i = 1 ; i <= nx ; i++)
    {
        nn [0] = 3*j*nx + 2*i + 2*j + 1 ;
        nn [1] = nn [0] - 1 ;
        nn [2] = nn [1] - 1 ;
        nn [3] = (3*j-1)*nx + 2*j + i - 1 ;
        nn [4] = 3*(j-1)*nx + 2*i + 2*j - 3 ;
        nn [5] = nn [4] + 1 ;
        nn [6] = nn [5] + 1 ;
        nn [7] = nn [3] + 1 ;
        for (int krow = 0 ; krow < 8 ; krow++) nn [krow]-- ;
        for (int krow = 0 ; krow < 8 ; krow++)
        {
            for (int kcol = 0 ; kcol < 8 ; kcol++)
            {
                I [ntriplets] = nn [krow] ;
                J [ntriplets] = nn [kcol] ;
                X [ntriplets] = em (krow,kcol) ;
                ntriplets++ ;
            }
        }
    }
}
// A = sparse (I,J,X,n,n) ;
GrB_Matrix_build (A, I, J, X, ntriplets, GrB_PLUS_FP64) ;

```

The `GrB_assign` version has the advantage of not requiring the user application to construct the tuple list, and is almost as fast as using `GrB_Matrix_build`. The code is more elegant than either the MATLAB `wathen.m` function or its GraphBLAS equivalent above. Its performance is comparable with the other two methods, but slightly slower, being about 5% slower than the MATLAB `wathen`, and 20% slower than the GraphBLAS method above.

```

GrB_Matrix_new (&F, GrB_FP64, 8, 8) ;

```

```

for (int j = 1 ; j <= ny ; j++)
{
    for (int i = 1 ; i <= nx ; i++)
    {
        nn [0] = 3*j*nx + 2*i + 2*j + 1 ;
        nn [1] = nn [0] - 1 ;
        nn [2] = nn [1] - 1 ;
        nn [3] = (3*j-1)*nx + 2*j + i - 1 ;
        nn [4] = 3*(j-1)*nx + 2*i + 2*j - 3 ;
        nn [5] = nn [4] + 1 ;
        nn [6] = nn [5] + 1 ;
        nn [7] = nn [3] + 1 ;
        for (int krow = 0 ; krow < 8 ; krow++) nn [krow]-- ;
        for (int krow = 0 ; krow < 8 ; krow++)
        {
            for (int kcol = 0 ; kcol < 8 ; kcol++)
            {
                // F (krow,kcol) = em (krow, kcol)
                GrB_Matrix_setElement (F, em (krow,kcol), krow, kcol) ;
            }
        }
        // A (nn,nn) += F
        GrB_assign (A, NULL, GrB_PLUS_FP64, F, nn, 8, nn, 8, NULL) ;
    }
}

```

Since there is no `Mask`, and since `GrB_REPLACE` is not used, the call to `GrB_assign` in the example above is identical to `GxB_subassign`. Either one can be used, and their performance would be identical.

Refer to the `wathen.c` function in the `Demo` folder, which uses GraphBLAS to implement the two methods above, and two additional ones.

## 17.4 Reading a matrix from a file

See also `LAGraph_mmread` and `LAGraph_mmwrite`, which can read and write any matrix in Matrix Market format, and `LAGraph_binread` and `LAGraph_binwrite`, which read/write a matrix from a binary file. The binary file I/O functions are much faster than the `read_matrix` function described here, and also much faster than `LAGraph_mmread` and `LAGraph_mmwrite`.

The `read_matrix` function in the `Demo` reads in a triplet matrix from a file, one line per entry, and then uses `GrB_Matrix_build` to create the matrix. It creates a second copy with `GrB_Matrix_setElement`, just to test

that method and compare the run times. Section 17.2 has already compared `build` versus `setElement`.

The function can return the matrix as-is, which may be rectangular or unsymmetric. If an input parameter is set to make the matrix symmetric, `read_matrix` computes  $A=(A+A')/2$  if  $A$  is square (turning all directed edges into undirected ones). If  $A$  is rectangular, it creates a bipartite graph, which is the same as the augmented matrix,  $A = \begin{bmatrix} 0 & A \\ A' & 0 \end{bmatrix}$ . If  $C$  is an  $n$ -by- $n$  matrix, then  $C=(C+C')/2$  can be computed as follows in GraphBLAS, (the `scale2` function divides an entry by 2):

```
GrB_Descriptor_new (&dt2) ;
GrB_set (dt2, GrB_TRAN, GrB_INP1) ;
GrB_Matrix_new (&A, GrB_FP64, n, n) ;
GrB_eWiseAdd (A, NULL, NULL, GrB_PLUS_FP64, C, C, dt2) ;    // A=C+C'
GrB_free (&C) ;
GrB_Matrix_new (&C, GrB_FP64, n, n) ;
GrB_UnaryOp_new (&scale2_op, scale2, GrB_FP64, GrB_FP64) ;
GrB_apply (C, NULL, NULL, scale2_op, A, NULL) ;             // C=A/2
GrB_free (&A) ;
GrB_free (&scale2_op) ;
```

This is of course not nearly as elegant as  $A=(A+A')/2$  in MATLAB, but with minor changes it can work on any type and use any built-in operators instead of `PLUS`, or it can use any user-defined operators and types. The above code in SuiteSparse:GraphBLAS takes 0.60 seconds for the `Freescalc2` matrix, slightly slower than MATLAB (0.55 seconds).

Constructing the augmented system is more complicated using the GraphBLAS C API Specification since it does not yet have a simple way of specifying a range of row and column indices, as in `A(10:20,30:50)` in MATLAB (`GxB_RANGE` is a SuiteSparse:GraphBLAS extension that is not in the Specification). Using the C API in the Specification, the application must instead build a list of indices first, `I=[10, 11 ... 20]`.

Thus, to compute the MATLAB equivalent of  $A = \begin{bmatrix} 0 & A \\ A' & 0 \end{bmatrix}$ , index lists `I` and `J` must first be constructed:

```
int64_t n = nrows + ncols ;
I = malloc (nrows * sizeof (int64_t)) ;
J = malloc (ncols * sizeof (int64_t)) ;
// I = 0:nrows-1
// J = nrows:n-1
if (I == NULL || J == NULL)
{
```

```

        if (I != NULL) free (I) ;
        if (J != NULL) free (J) ;
        return (GrB_OUT_OF_MEMORY) ;
    }
    for (int64_t k = 0 ; k < nrows ; k++) I [k] = k ;
    for (int64_t k = 0 ; k < ncols ; k++) J [k] = k + nrows ;

```

Once the index lists are generated, however, the resulting GraphBLAS operations are fairly straightforward, computing  $A = \begin{bmatrix} 0 & C \\ C' & 0 \end{bmatrix}$ .

```

GrB_Descriptor_new (&dt1) ;
GrB_set (dt1, GrB_TRAN, GrB_INP0) ;
GrB_Matrix_new (&A, GrB_FP64, n, n) ;
// A (nrows:n-1, 0:nrows-1) = C'
GrB_assign (A, NULL, NULL, C, J, ncols, I, nrows, dt1) ;
// A (0:nrows-1, nrows:n-1) = C
GrB_assign (A, NULL, NULL, C, I, nrows, J, ncols, NULL) ;

```

This takes 1.38 seconds for the `Freescape2` matrix, almost as fast as  $A = \begin{bmatrix} \text{sparse}(m,m) & C \\ C' & \text{sparse}(n,n) \end{bmatrix}$  in MATLAB (1.25 seconds). The `GxB_Matrix_concat` function would be faster still (this example was written prior to `GxB_Matrix_concat` was added to SuiteSparse:GraphBLAS).

Both calls to `GrB_assign` use no accumulator, so the second one causes the partial matrix  $A = \begin{bmatrix} 0 & 0 \\ C' & 0 \end{bmatrix}$  to be built first, followed by the final build of  $A = \begin{bmatrix} 0 & C \\ C' & 0 \end{bmatrix}$ . A better method, but not an obvious one, is to use the `GrB_FIRST_FP64` accumulator for both assignments. An accumulator enables SuiteSparse:GraphBLAS to determine that that entries created by the first assignment cannot be deleted by the second, and thus it need not force completion of the pending updates prior to the second assignment.

SuiteSparse:GraphBLAS also adds a `GxB_RANGE` mechanism that mimics the MATLAB colon notation. This speeds up the method and simplifies the code the user needs to write to compute  $A = \begin{bmatrix} 0 & C \\ C' & 0 \end{bmatrix}$ :

```

int64_t n = nrows + ncols ;
GrB_Matrix_new (&A, xtype, n, n) ;
GrB_Index I_range [3], J_range [3] ;
I_range [GxB_BEGIN] = 0 ;
I_range [GxB_END ] = nrows-1 ;
J_range [GxB_BEGIN] = nrows ;
J_range [GxB_END ] = ncols+nrows-1 ;
// A (nrows:n-1, 0:nrows-1) += C'
GrB_assign (A, NULL, GrB_FIRST_FP64, // or NULL,
            C, J_range, GxB_RANGE, I_range, GxB_RANGE, dt1) ;

```

```
// A (0:nrows-1, nrow:n-1) += C
GrB_assign (A, NULL, GrB_FIRST_FP64, // or NULL,
            C, I_range, GxB_RANGE, J_range, GxB_RANGE, NULL) ;
```

Any operator will suffice because it is not actually applied. An operator is only applied to the set intersection, and the two assignments do not overlap. If an accum operator is used, only the final matrix is built, and the time in GraphBLAS drops slightly to 1.25 seconds. This is a very small improvement because in this particular case, SuiteSparse:GraphBLAS is able to detect that no sorting is required for the first build, and the second one is a simple concatenation. In general, however, allowing GraphBLAS to postpone pending updates can lead to significant reductions in run time.

## 17.5 User-defined types and operators

The `Demo` folder contains two working examples of user-defined types, first discussed in Section 6.1.1: `double complex`, and a user-defined `typedef` called `wildtype` with a `struct` containing a string and a 4-by-4 `float` matrix.

**Double Complex:** Prior to v3.3, GraphBLAS did not have a native complex type. It now appears as the `GxB_FC64` predefined type, but a complex type can also easily added as a user-defined type. The `Complex_init` function in the `usercomplex.c` file in the `Demo` folder creates the `Complex` type based on the C11 `double complex` type. It creates a full suite of operators that correspond to every built-in GraphBLAS operator, both binary and unary. In addition, it creates the operators listed in the following table, where  $D$  is `double` and  $C$  is `Complex`.

name	types	MATLAB/Octave equivalent	description
<code>Complex_complex</code>	$D \times D \rightarrow C$	<code>z=complex(x,y)</code>	complex from real and imag.
<code>Complex_conj</code>	$C \rightarrow C$	<code>z=conj(x)</code>	complex conjugate
<code>Complex_real</code>	$C \rightarrow D$	<code>z=real(x)</code>	real part
<code>Complex_imag</code>	$C \rightarrow D$	<code>z=imag(x)</code>	imaginary part
<code>Complex_angle</code>	$C \rightarrow D$	<code>z=angle(x)</code>	phase angle
<code>Complex_complex_real</code>	$D \rightarrow C$	<code>z=complex(x,0)</code>	real to complex real
<code>Complex_complex_imag</code>	$D \rightarrow C$	<code>z=complex(0,x)</code>	real to complex imag.

The `Complex_init` function creates two monoids (`Complex_add_monoid` and `Complex_times_monoid`) and a semiring `Complex_plus_times` that corresponds to the conventional linear algebra for complex matrices. The include file `usercomplex.h` in the `Demo` folder is available so that this user-

defined `Complex` type can easily be imported into any other user application. When the user application is done, the `Complex_finalize` function frees the `Complex` type and its operators, monoids, and semiring. NOTE: the `Complex` type is not supported in this Demo in Microsoft Visual Studio.

**Struct-based:** In addition, the `wildtype.c` program creates a user-defined `typedef` of a `struct` containing a dense 4-by-4 `float` matrix, and a 64-character string. It constructs an additive monoid that adds two 4-by-4 dense matrices, and a multiplier operator that multiplies two 4-by-4 matrices. Each of these 4-by-4 matrices is treated by GraphBLAS as a “scalar” value, and they can be manipulated in the same way any other GraphBLAS type can be manipulated. The purpose of this type is illustrate the endless possibilities of user-defined types and their use in GraphBLAS.

## 17.6 User applications using OpenMP or other threading models

An example demo program (`context_demo`) is included that illustrates how a multi-threaded user application can use GraphBLAS, where each user thread calls GraphBLAS simultaneously, with nested parallelism.

GraphBLAS can also be combined with user applications that rely on MPI, the Intel TBB threading library, POSIX pthreads, Microsoft Windows threads, or any other threading library. If GraphBLAS itself is compiled with OpenMP, it will be thread safe when combined with other libraries. See Section [10.2.2](#) for thread-safety issues that can occur if GraphBLAS is compiled without OpenMP.

## 18 Compiling and Installing SuiteSparse:GraphBLAS

### 18.1 Quick Start

GraphBLAS requires `cmake` version 3.20 or later. It optionally can use OpenMP for best performance. For OpenMP on the Mac, see Section 18.4.6. Without OpenMP, GraphBLAS will be significantly slower since it is a highly parallel package.

A `cmake` build system is available for Linux, Mac, and Windows. For Linux or Mac, a simple Makefile wrapper is available that accesses this `cmake` build system. Simply do:

```
make
sudo make install
```

For Windows, open CMake and use the provided `CMakeLists.txt` file to build GraphBLAS in the `GraphBLAS/build` folder.

Next, try the demos with `make demos`. The output of the demos will be compared with expected output files in `Demo/Output`.

### 18.2 Requirements

GraphBLAS requires `cmake` version 3.20 or later. It uses OpenMP for best performance (this is STRONGLY recommended, but GraphBLAS can be compiled without it). It requires the `lz4` and `zstd` compression packages, and optionally uses the `cpu_features` package by Google; all of these are bundled with the GraphBLAS source.

Using the GraphBLAS JIT has many requirements, but it greatly increases performance, particularly with user-defined types and operators, and when typecasting is done with built-in types and operators.

The `cmake` build script sets up the JIT to use the compiler and compiler flags used to build GraphBLAS itself. If the target environment does not have a compiler (the Apple iPad for example), then the JIT will not work.

The JIT requires access to a cache folder, which should be preserved even after a program that uses GraphBLAS finishes, so that JIT kernels do not have to continually be recompiled. By default the folder is `~/.SuiteSparse/GrBX.Y.Z` on Linux/Mac, where `X.Y.Z` is the version of GraphBLAS you have. On Windows, the location is determined by your `LOCALAPPDATA` environment variable, where the folder is `SuiteSparse/GrBX.Y.Z` inside that location.

File locking is required, so if the file system does not support file locking, the JIT will not work and performance will suffer (the `make demos` will fail since it tests this condition). If this occurs, try making your `SuiteSparse` cache folder a link to another a location on another file system that supports file locking, or set an environment variable, `GRAPHBLAS_CACHE_PATH`, to point to your a cache folder location on a file system that supports file locking. See Section [9.1.11](#) for more details.

## 18.3 Installing GraphBLAS for MATLAB/Octave

See the `GraphBLAS/GraphBLAS/README.md` file for instructions on how to compiler the MATLAB/Octave interface on Linux/Mac/Windows.

## 18.4 More details

### 18.4.1 On Linux and Mac

GraphBLAS makes extensive use of features in the C11 standard, and thus a C compiler supporting this version of the C standard is required to use all features of GraphBLAS.

**Any version of the Intel `icx` compiler is highly recommended.**

In most cases, the Intel `icx` and the Intel OpenMP library (`libiomp`) result in the best performance. The `gcc` and the GNU OpenMP library (`libgomp`) generally gives good performance: typically on par with `icx` but in a few special cases significantly slower. The Intel `icc` compiler is not recommended; it results in poor performance for `#pragma omp atomic`.

If you are using a C compiler that does not support the C11 standard, such as `cl` in Microsoft Visual Studio, then the `_Generic` keyword is not available. `SuiteSparse:GraphBLAS` will still compile, but you will not have access to polymorphic functions such as `GrB_assign`. You will need to use the non-polymorphic functions instead.

To compile `SuiteSparse:GraphBLAS`, simply type `make` in the main GraphBLAS folder, which compiles the library with your default system compiler. This compile GraphBLAS using 8 threads, which will take a long time. To compile with more threads (40, for this example), use:

```
make JOBS=40
```

To use a non-default compiler with 4 threads:

```
make CC=icx CXX=icpx JOBS=4
```

GraphBLAS v6.1.3 and later use the `cpu_features` package by Google to determine if the target architecture supports AVX2 and/or AVX512F (on Intel x86\_64 architectures only). In case you have build issues with this package, you can compile without it (and then AVX2 and AVX512F acceleration will not be used):

```
make CMAKE_OPTIONS='-DGBNCPUFAT=1'
```

Without `cpu_features`, it is still possible to enable AVX2 and AVX512F. Rather than relying on run-time tests, you can use these flags to enable both AVX2 and AVX512F, without relying on `cpu_features`:

```
make CMAKE_OPTIONS='-DGBNCPUFAT=1 -DGBAVX2=1 -DGBAVX512F=1'
```

To use multiple options, separate them by a space. For example, to build just the library but not `cpu_features`, and to enable AVX2 but not AVX512F, and use 40 threads to compile:

```
make CMAKE_OPTIONS='-DGBNCPUFAT=1 -DGBAVX2=1' JOBS=40
```

After compiling the library, you can compile the demos with `make all` and then `make demos` while in the top-level GraphBLAS folder.

If `cmake` or `make` fail, it might be that your default compiler does not support C11. Try another compiler. For example, try one of these options. Go into the `build` directory and type one of these:

```
CC=gcc cmake ..
CC=gcc-11 cmake ..
CC=xlc cmake ..
CC=icx cmake ..
```

You can also do the following in the top-level GraphBLAS folder instead:

```
CC=gcc make
CC=gcc-11 make
CC=xlc make
CC=icx make
```

For faster compilation, you can specify a parallel make. For example, to use 32 parallel jobs and the `gcc` compiler, do the following:

```
JOBS=32 CC=gcc make
```

#### 18.4.2 On the Mac (Intel or ARM)

GraphBLAS requires `cmake` v3.20 or later, and it optionally uses `make` to simplify the use of the `cmake` build system. It also needs other Apple Command Line Tools from Xcode. First install Xcode (see <https://developer.apple.com/xcode>), and then install the command line tools for Xcode:

```
xcode-select --install
```

Next, install `brew`, at <https://brew.sh>, or `spack`. Use `brew` or `spack` to install `cmake` version 3.20 or later.

#### 18.4.3 On the Intel-based Mac

If you have the Intel compiler and its OpenMP library, then use the following in the top-level GraphBLAS folder. The Intel OpenMP library will be found automatically:

```
make CC=icc CXX=icpc
```

#### 18.4.4 On IBM Power

Do not use `gcc` to compile GraphBLAS. At least versions up to 14.2.0 have a bug in the atomic capture on the IBM Power8 (see the comments in the `Source/mxm/factory` folder). Use `clang` or `xlc` instead.

#### 18.4.5 On Microsoft Windows

SuiteSparse:GraphBLAS can be compiled by the Microsoft C compiler (`cl`) using Microsoft Visual Studio. However, that compiler is not C11 compliant. As a result, GraphBLAS on Windows will have a few minor limitations.

- The MS Visual Studio compiler does not support the `_Generic` keyword, required for the polymorphic GraphBLAS functions. So for example, you will need to use `GrB_Matrix_free` instead of just `GrB_free`.
- Variable-length arrays are not supported, so user-defined types are limited to 1024 bytes in size. This can be changed by editing `GB_VLA_MAXSIZE` in `Source/GB_compiler.h`, and recompiling SuiteSparse:GraphBLAS.
- AVX acceleration is not enabled.

- You must compile with 64-bit computing enabled (x64). Otherwise, a compiler error will occur (`InterlockedExchange64`, `InterlockedOr64` and other methods will not be found).

If you use a recent `gcc` or `icx` compiler on Windows other than the Microsoft Compiler (`cl`), these limitations can be avoided.

The following instructions apply to Windows 10, CMake 3.16, and Visual Studio 2019, but may work for earlier versions.

1. Install CMake 3.16 or later, if not already installed. See <https://cmake.org/> for details.
2. Install Microsoft Visual Studio, if not already installed. See <https://visualstudio.microsoft.com/> for details. Version 2019 is preferred, but earlier versions may also work.
3. Open a terminal window and type this in the `GraphBLAS/build` folder:

```
cmake ..
```

Alternatively, use the `cmake` gui program to configure the cmake build system for GraphBLAS.

4. The `cmake` command generates many files in `GraphBLAS/build`, and the file `graphblas.sln` in particular. Open the generated `graphblas.sln` file in Visual Studio.
5. Optionally: right-click `graphblas` in the left panel (Solution Explorer) and select properties; then navigate to **Configuration Properties**, **C/C++**, **General** and change the parameter **Multiprocessor Compilation** to **Yes (/MP)**. Click **OK**. This will significantly speed up the compilation of GraphBLAS.
6. Select the **Build** menu item at the top of the window and select **Build Solution**. This should create a folder called **Release** and place the compiled `graphblas.dll`, `graphblas.lib`, and `graphblas.exp` files there. Please be patient; some files may take a while to compile and sometimes may appear to be stalled. Just wait.
7. Alternatively, instead of opening Visual Studio, type this command in the terminal window while in the `build` folder:

```
cmake --build . --config Release
```

8. Add the `GraphBLAS/build/Release` folder to the Windows System path:

- Open the `Start Menu` and type `Control Panel`.
- Select the `Control Panel` app.
- When the app opens, select `System and Security`.
- Under `System and Security`, select `System`.
- From the top left side of the `System` window, select `Advanced System Settings`. You may have to authenticate at this step. If you cannot authenticate, try setting the User Environment Variables instead.
- The `Systems Properties` window should appear with the `Advanced` tab selected; select `Environment Variables`.
- The `Environment Variables` window displays 2 sections, one for `User` variables and the other for `System` variables. Under the `Systems` variable section, scroll to and select `Path`, then select `Edit`. A editor window appears allowing to add, modify, delete or re-order the parts of the `Path`.
- Add the full path of the `GraphBLAS\build\Release` folder (typically starting with `C:\Users\you\...`, where `you` is your Windows username) to the `Path`. To use the MATLAB interface, add the full path of the `GraphBLAS\GraphBLAS\build\Release` folder as well.
- If the above steps do not work, you can instead copy the `graphblas.*` files from `GraphBLAS\build\Release` into any existing folder listed in your `Path`.

9. The `GraphBLAS/Include/GraphBLAS.h` file must be included in user applications via `#include "GraphBLAS.h"`. This is already done for you in the MATLAB/Octave interface discussed in the next section.

#### 18.4.6 Mac using clang

To use OpenMP with clang on the Mac, you can use one of two options:

- Using brew: this is recommended, since Octave on the Mac requires it. Install brew (see <https://brew.sh>), then do

```
brew install libomp
```

Add the following to your `~/.zshrc` file:

```
export OpenMP_ROOT=$(brew --prefix)/opt/libomp
```

Next, restart your terminal shell before using `cmake` or Octave to compile GraphBLAS.

- Using the R-project via <https://mac.r-project.org/openmp/>. Be sure to check that page for the OpenMP version that matches your version of Apple Xcode. For example, if using Xcode 13.3 to 13.4.1, use:

```
curl -O https://mac.r-project.org/openmp/openmp-13.0.0-darwin21-Release.tar.gz
sudo tar fvxz openmp-13.0.0-darwin21-Release.tar.gz -C /
```

These commands will install universal binaries (ARM and x86) for `libomp.dylib`, and the following files:

```
/usr/local/lib/libomp.dylib
/usr/local/include/ompt.h
/usr/local/include/omp.h
/usr/local/include/omp-tools.h
```

Once you do this, the GraphBLAS cmake build system should find this copy of OpenMP for clang. However, if you use this version of the OpenMP library, GraphBLAS will fail when used in Octave.

#### 18.4.7 Linking issues after installation

My previous Linux distro (Ubuntu 18.04) included a copy of `libgraphblas.so.1`, which is SuiteSparse:GraphBLAS v1.1.2. After installing SuiteSparse:GraphBLAS in `/usr/local/lib` (with `sudo make install`), compiling a simple stand-alone program links against `libgraphblas.so.1` instead of the latest version, while at the same time accessing the latest version of the include file as `/usr/local/include/GraphBLAS.h`. This command fails:

```
gcc prog.c -lgraphblas
```

Revising my `LD_LIBRARY_PATH` to put `/usr/local/lib` first in the library directory order didn't help. If you encounter this problem, try one of the following options (all four work for me, and link against the proper version, `/usr/local/lib/libgraphblas.so.10.0.3` for example):

```
gcc prog.c -l:libgraphblas.so.10
gcc prog.c -l:libgraphblas.so.10.0.3
gcc prog.c /usr/local/lib/libgraphblas.so
gcc prog.c -Wl,-v -L/usr/local/lib -lgraphblas
```

This `prog.c` test program is a trivial one, which works in v1.0 and later:

```
#include <GraphBLAS.h>
int main (void)
{
    GrB_init (GrB_NONBLOCKING) ;
    GrB_finalize ( ) ;
}
```

Compile the program above, then use this command to ensure `libgraphblas.so.10` appears:

```
ldd a.out
```

#### 18.4.8 Running the tests

To run a short test, type `make demo` at the top-level `GraphBLAS` folder. This will run all the demos in `GraphBLAS/Demos`. MATLAB is not required.

To perform the extensive tests in the `Test` folder, and the statement coverage tests in `Tcov`, MATLAB R2018a or later is required. See the `README.txt`

files in those two folders for instructions on how to run the tests. The tests in the `Test` folder have been ported to MATLAB on Linux, MacOS, and Windows. The `Tcov` tests do not work on Windows. The MATLAB/Octave interface test (`gbtest`) works on all platforms; see the `GraphBLAS/GraphBLAS` folder for more details.

#### 18.4.9 Cleaning up

To remove all compiled files, type `make distclean` in the top-level `GraphBLAS` folder.

## 19 Release Notes

- Apr 7, 2025: version 10.0.3
  - upgrade `xxHash` to 0.8.3: contributed by Christoph Grüninger.
  - upgrade `cpu_features` to 0.9.0: contributed by Christoph Grüninger.
  - Octave interface: revised for the recent MacOS (15.3.2), assuming that both Octave and OpenMP are installed via homebrew.
- Mar 20, 2025: version 10.0.2
  - performance: improved the performance of `GrB_setElement` when many entries are inserted into a matrix that is initially empty.
  - (61) bug fix: `GxB_Serialized_get_Scalar` declared twice in `GraphBLAS.h`; caught by Erik Welch.
- Mar 6, 2025: version 10.0.1
  - (60) bug fix: one of the `GrB_mxm` kernels (`saxpy4`) can hit a segfault for user-defined types, in the JIT kernels. Caught by Gabe Gomez.
- Mar 1, 2025: version 10.0.0
  - 32/64 bit matrices and vectors: the `GrB_Matrix` and `GrB_Vector` now exploit 32-bit integers when possible. New methods added to pass 32-bit integer arrays to/from `GrB_build`, `extract`, `assign`,

`subassign`, and `extractTuples`. New object, the `GxB_Container` added for fast import/export of matrices/vectors with arbitrary integer content.

- `GrB_Field`: this enum is strongly deprecated, and replaced with `typedef int GrB_Field`. This is an upward-compatible change to the API, and will allow the creation of a future mathematical field object in GraphBLAS. This type should not be used; use an `int` instead. It will be replaced in a future version of GraphBLAS.
- enum parameters: replaced all enum parameters with `int`, to simplify future updates to enum parameters, including the `GrB_Field`.
- `GxB_JIT_ERROR`: added in 9.4.x, changed value to avoid conflict with LAGraph error codes.
- `pack/unpack`: these are declared historical; they still work but use 64-bit integers only. Use the new `GxB_Container` methods instead.
- `GxB_Matrix_iso` and `GxB_Vector_iso`: declared historical; use `GrB_get` with the new `GxB_ISO` enum.
- `GxB_Matrix_type`, `GxB_Vector_type`, `GxB_Scalar_type`: no longer historical; added back to the user guide.
- Summary: the API is upward-compatible with 9.4.x, but only after the user application is recompiled with GraphBLAS v10.0.0. As a result, the SO version must increase from 9 to 10.

- Feb 20, 2025: version 9.4.5

- (59) bug fix: the `GxB_NO_INT32` and `GxB_NOT_INT64` flags in `GB_control.h` did not completely remove some of the INT32 and INT64 factory kernels. Caught by Erik Welch, NVIDIA.
- workaround for an AppleClang compiler bug: On the Mac, the `Source/mask/GB_masker.c` file triggers a bug in AppleClang 16.0.0 with `-O3` in (MacOS 14.6.1 (23G93), Xcode 16.2, Apple clang version 16.0.0, clang-1600.0.26.6). It also fails in MacOS 15.2 (Target: arm64-apple-darwin23.6.0). The bug is triggered by these tests in LAGraph (v1.2 branch, unreleased, Jan 4, 2025):

```

39 - LAGraphX_BF (SIGTRAP)
40 - LAGraphX_Coarsen_Matching (Failed)
41 - LAGraphX_FastGraphletTransform (SIGTRAP)
49 - LAGraphX_PageRankGX (SIGTRAP)
54 - LAGraphX_SquareClustering (SIGTRAP)
61 - LAGraphX_msf (Failed)

```

When using clang, optimization is turned off for this file. This has no impact on performance since `GB_masker.c` is very simple, consisting of a single sequence of calls to other methods.

- Feb 17, 2024: version 9.4.4
  - (58) bug fix: semirings with user-defined monoids and the `GrB_ONEB` or `GxB_PAIR` operators caused a JIT compiler error. Caught by Gabe Gomez.
  - (57) bug fix: `GraphBLAS.h` header: remove duplicate definitions of `GxB_MAX_FIRST_*` semirings (incompletely moved to 'historical' section in 9.4.2).
- Nov 20, 2024: version 9.4.2
  - clarified User Guide: regarding when the hyper-hash is built
  - JIT: reduced JIT kernel encodings
  - (also includes the updates from 9.4.0.beta and 9.4.1.beta listed below).
- Nov 15, 2024: version 9.4.1 (only released as BETA)
  - More JIT kernels: all JIT kernels for `GrB_assign`, `GxB_subassign`, `GrB_extract`, `GxB_sort`, `GrB_kronecker`, the stand-alone mask phase (an internal method that computes  $\mathbf{C}(\mathbf{M}) = \mathbf{Z}$ ), and utilities have been created. All kernels formerly tagged in the code as `JIT: needed` are now finished.
  - removed Factory kernels for: types `int8` and `uint8`, and semirings: `max_min`, `max_plus`, `max_times`, `min_max`, `min_times`, `plus_min`, `plus_max`, non-Boolean `land/lor/lxor/lxnor`, and integer `times_first/second`,

to reduce size of compiled library. JIT kernels will be used instead for these types and semirings.

- `GxB_IndexBinaryOp`: finalized and named as `GxB_*`.
- Oct 15, 2024: version 9.4.0 (only released as BETA)
  - new operator and associated methods: added the draft `G*B_IndexBinaryOp`.
  - JIT error-handling behavior changed: if a compiler error occurs in the JIT, `GxB_JIT_ERROR` is now returned. Previously, GraphBLAS would fall back to a generic method if such an error occurred.
- Aug 12, 2024: version 9.3.1
  - (56) bug fix: wrong type for `fgetc` return value in `JITpackage`; leads to infinite loop on some systems when building GraphBLAS.
- Aug 2, 2024: version 9.3.0
  - code restructuring: Source folder split into many subfolders, and some files and internal functions renamed. No visible external change.
  - (55) bug fix: `GrB_apply` with user-defined index-unary op and generic kernel.
  - (54) bug fix: reducing a huge iso full matrix to a scalar resulted in integer overflow if `nrows*ncols` was larger than about  $2^{60}$ .
  - reduced size of compiled library: `int16` and `uint16` types and operators for `FactoryKernels` are disabled in `GB_control.h`. The JIT will always be used instead.
- May 22, 2024: version 9.2.0
  - Added `graphblas_install.m` for a simpler method of compiling the MATLAB/Octave interface for GraphBLAS.
  - JIT: sanitizing the JIT cache path, better burble for compiler errors.
  - `GrB_get/GrB_set`: better handling of concurrent get/set between different user threads.

- Mar 22, 2024: version 9.1.0
  - minor updates to build system
  - C11 complex type detection: this is now detected and configured by cmake, instead of using an `#if ...` in the GraphBLAS.h header. This change was required to port GraphBLAS to the clang-cl compiler on Windows when it simulates the MSVC compiler. Also added a new feature (thus the minor version update to 9.1.0): `GxB_HAVE_COMPLEX*` to GraphBLAS.h to indicate which kind of complex data types are available in C11 or MSVC. Contributed by Markus Mützel.
  - (53) bug fix: `eWiseAdd C<M>=A+B` when M, A, and B are all hypersparse; access to M was incorrect (also affects `C<M>+=T` for any operation, if M and T are both hypersparse).
- Mar 1, 2024: version 9.0.3
  - (52) performance bug fix: JIT kernels since v8.3.1 were not compiled with OpenMP.
- Feb 26, 2024: version 9.0.2
  - GraphBLAS/Makefile `make static` was incorrect.
- Jan 20, 2024: version 9.0.1
  - minor updates to build system
- Version 9.0.0, Jan 10, 2024
  - `GrB_get/GrB_set`: new functions from the v2.1 C API.
  - `GrB_Type_new`, `GrB_UnaryOp_new`, `GrB_IndexUnaryOp_new`: no longer macros, since `GrB_set` can be used to set the names of the operators. These methods no longer extract the name, so the default name is now the empty string. This is because `GrB_get/set` can only set these names once. This is a non-compatible change of behavior for these 3 methods, so SuiteSparse:GraphBLAS must become v9.0.0.

- historical methods: many methods are replaced by `GrB_get` and `GrB_set`. They remain in `SuiteSparse:GraphBLAS` but have been declared historical. Terse prototypes exist in `GraphBLAS.h`, and any discussion is removed from the User Guide: `GxB_get`, `GxB_set`, and the methods they call, and many more. Use `GrB_get/set` in place those methods, and for: `GxB_*type_name`, `GxB_*type`, `GxB_Monoid_operator`, `GxB_Monoid_identity`, `GxB_Monoid_terminal`, `GxB_Semiring_add`, `GxB_Semiring_multiply`. Use `GrB_STORAGE_ORIENTATION_HINT` in place of `GxB_FORMAT`.
- `hyper_hash`: constructed only if the number of non-empty vectors in a hypersparse matrix is large ( $> 1024$ , by default).
- minor updates to build system: `*.pc` files for `pkgconfig`
- Dec 30, 2023: version 8.3.1
  - remove `#undef I` from `GraphBLAS.h`, so as not to conflict with the definition of `I` from `complex.h`.
  - major change to build system: by Markus Mützel
- Oct 7, 2023: version 8.2.1
  - (49) bug fix: `GrB_mxm saxpy4` and `saxpy5` had incorrectly handling of typecasting in v8.0.0 to v8.2.0 (caught by Erik Welch)
  - cross-compiler support: replace `check_c_source_runs` with `_compiles` for `GraphBLAS` and `SuiteSparse-config`, and remove check for `getenv("HOME")`.
  - cmake update: add "None" build type, from Antonio Rojas, for Arch Linux
- Version 8.2.0, Sept 8, 2023
  - cmake updates: `SuiteSparse::` namespace by Markus Mützel.
- Version 8.0.2, June 16, 2023
  - added `-DJITINIT=option`: use `-DJITINIT` to set the initial state of the `GxB_JIT_C_CONTROL` (4:on, 3:load, 2:run, 1:pause, 0:off). The default is 4 (on) if the JIT is enabled, or 2 (run) if `-DNJIT=1` is set.

- xxHash: upgraded to latest version as of June 16, 2023
- Version 8.0.1, May 27, 2023
  - (48) bug fix: `GrB*_nvals` returned `UINT64_MAX` ('infinity') for a `GrB_Vector` of size  $n$ -by- $2^{60}$ ; it should return  $2^{60}$ . Caught by Erik Welch, NVIDIA.
  - added `GxB_Context_error` and `GxB_Context_wait`
  - C++: changed complex typedefs for C++ that include GraphBLAS.h. Update from Markus Mützel.
- Version 8.0.0 (May 18, 2023)
  - version 8: This version is a major SO version increase, since it removes a few minor user-visible features from SuiteSparse:GraphBLAS: the `GrB_Descriptor` no longer supports threading control, and some features of the `GxB_SelectOp` are removed (see below). Enum values have been changed for compatibility with the upcoming `GrB_set/get` features in the V2.1 C API.
  - The JIT: GraphBLAS v8.0.0 includes a JIT for the CPU kernels, which can compile kernels at run-time. Added `GxB_set/get` options and environment variables to control the JIT. The `GxB_*Op_new` methods can accept NULL function pointers, if the strings are provided, valid, and the JIT is enabled.
  - `GxB_Type_new`: the size of the type can be given as zero, in which case the size is determined via a JIT kernel.
  - `GxB_UnaryOp_new`, `GxB_BinaryOp_new`, and `GxB_IndexUnaryOp_new`: the function pointer can be given as NULL, in which case the function is created by the JIT.
  - math kernels: revised for CUDA JIT. More accurate complex floating-point for Mac OS on Apple Silicon.
  - `Demo/wildtype_demo`: change to double so that CPU and GPU versions compute the same result.
  - `GxB_get`: can return `malloc/calloc/realloc/free`

- **GxB\_Context**: an object for controlling computational resources: number of OpenMP threads, the chunk factor, and (draft) GPU id.
  - **GrB\_Descriptor**: removed ability to control the number of OpenMP threads from the descriptor (a rarely used feature). Replaced with the **GxB\_Context** object.
  - **GxB\_SelectOp**: GraphBLAS no longer supports user-defined **GxB\_SelectOps**. Use a **GrB\_IndexUnaryOp** instead. The **GxB\_SelectOp\_new** and **GxB\_SelectOp\_free** functions are removed entirely. The built-in **GxB\_SelectOps**, **GxB\_Matrix\_select**, **GxB\_Vector\_select**, and **GxB\_select** still work. However, the **GxB\_EQ\_THUNK**, **GxB\_EQ\_ZERO**, **GxB\_NE\_THUNK**, and **GxB\_NE\_ZERO** operators no longer work on user-defined types, as they did in v7.4.4 and earlier. Create a user-defined **GrB\_IndexUnaryOp** to compute these operations instead, and use **GrB\_select**.
  - **alternative/Makefile**: removed; not compatible with the JIT.
  - **zstd**: upgraded to v1.5.5 (Apr 4, 2023)
- Version 7.4.4 (Mar 25, 2023)
    - (47) bug fix: OpenMP atomics require **seq\_cst** on the ARM. Revised **GB\_atomics.h** accordingly, and added them for all architectures (caught by Gábor Szárnyas).
  - Version 7.4.3 (Jan 20, 2023)
    - debug: turned on in **GrB\_Matrix\_removeElement** by mistake.
  - Version 7.4.2 (Jan 17, 2023)
    - minor change to build system: for SuiteSparse v7.0.0.
    - deprecation notice: in GraphBLAS v8.0.0, the ability to set the number of threads, and chunk size, in the descriptor will be removed. It still appears in v7.x, but will be replaced by a Context object in v8.0.0.
  - Version 7.4.1 (Dec 29, 2022)

- global free pool: disabled. Benefit for single-thread user applications was modest, and it causes too much contention in a critical section when the user application is multi-threaded.
- `GrB_mxm`: revised task creation heuristics for sparse-times-sparse for better performance.
- Version 7.4.0 (Dec 23, 2022)
  - add non-`va_arg` methods: `va_arg`-based `GxB_get/set` methods are C11 but cause issues for `ffi` in Python. As a temporary workaround, new methods have been added that do not use `va_arg`. The existing `GxB_get/set` methods are not changed. The new methods are not in the user guide, since all of the `GxB_get/set` methods will be superceded with `GrB_get/set` in the v2.1 C API. At that point, all `GxB_get/set` methods will become historical (kept, not deprecated, but removed from the user guide).
- Version 7.3.3 (Dec 9, 2022)
  - `stdatomic.h`: using `#include <stdatomic.h>` and `atomic_compare_exchange_weak` instead of GCC/clang/icx `__atomic_*` variants. Added `-latomic` if required.
  - chunk factor for `C=A*B` (`saxpy3` method): revised for non-builtin-semirings
- Version 7.3.2 (Nov 12, 2022)
  - `cmake_modules`: minor revision to build system, to sync with SuiteSparse v6.0.0
  - Added option `-DNOOPENMP=1` to disable OpenMP parallelism.
- Version 7.3.1 (Oct 21, 2022)
  - workaround for a bug in the Microsoft Visual Studio Compiler, MSC 19.2x (in vs2019).
- Version 7.3.0 (Oct 14, 2022)
  - `GrB_Matrix`: changes to the internal data structure

- minor internal changes: `A->nvals` for sparse/hypersparse
  - more significant changes: added hyper-hash for hypersparse case, speeds up many operations on hypersparse matrices. Based on [Gre21].
  - `GxB_unpack_HyperHash` and `GxB_pack_HyperHash`: to pack/unpack the hyper-hash
  - `@GrB` MATLAB/Octave interface: changed license to Apache-2.0.
  - MATLAB library: renamed to `libgraphblas_matlab.so`
  - performance: faster `C=A*B` when using a single thread and `B` is a sparse vector with many entries.
- Version 7.2.0 (Aug 8, 2022)
    - added ZSTD as a compression option for serialize/deserialize: Version 1.5.3 by Yann Collet, <https://github.com/facebook/zstd.git>. Copyright (c) 2016-present, Facebook, Inc. All rights reserved. Included in SuiteSparse:GraphBLAS via its BSD-3-clause license. The default method is now ZSTD, level 1.
    - `GxB_Matrix_reshape*` added.
    - MATLAB interface: `reshape`, `C(:)=A`, `C=A(:)` are faster. Better error messages.
  - Version 7.1.2 (July 8, 2022)
    - MATLAB interface: linear indexing added for `C(:)=A`, `C=A(:)`, and single-output `I=find(C)`. Faster bandwidth, `istriu`, `istril`, `isbanded`, `isdiag`. `C(I,J)=A` can now grow the size of `A`.
  - Version 7.1.1 (June 3, 2022)
    - minor updates to documentation and error messages
    - MATLAB interface: minor revision of `GrB.deserialize`
  - Version 7.1.0 (May 20, 2022)
    - added cube root: `GxB_CBRT_FP32` and `GxB_CBRT_FP64` unary operators
    - added `GxB_Matrix_isStoredElement` and `GxB_Vector_isStoredElement`

- Version 7.0.4 (Apr 25, 2022)
  - (46) bug fix: user-defined type size was incorrectly limited to 128 bytes. Caught by Erik Welch.
- Version 7.0.3 (Apr 8, 2022)
  - faster transpose when using 2 threads
- Version 7.0.2 (Apr 5, 2022)
  - (45) bug fix: vector iterator was broken for iterating across a vector in bitmap format. Caught by Erik Welch.
- Version 7.0.1 (Apr 3, 2022)
  - added revised ACM TOMS submission to the Doc folder
- Version 7.0.0 (Apr 2, 2022)
  - (44) spec bug: `GrB_Matrix_diag` was implemented in v5.2.x and v6.x with the wrong signature. This fix requires the major release to change, from v6.x to v7.x.
  - (43) performance bug fix for `GrB_mxm`: auto selection for saxpy method (Hash vs Gustavson) revised.
  - `GrB_assign`: better performance for `C(i,j)=scalar` and `C(i,j)+=scalar` when `i` and `j` have length 1 (scalar assignment with no scalar expansion).
- Version 6.2.5 (Mar 14, 2022)
  - For SuiteSparse v5.11.0.
- Version 6.2.4 (Mar 8, 2022)
  - (42) bug fix: `GrB_mxm` with 0-by-0 iso full matrices. Caught by Henry Amuasi in the Python grblas interface, then triaged and isolated by Erik Welch.
- Version 6.2.3 (Mar 5, 2022)

- minor update to documentation in `GrB.build`: no change to any code
- Version 6.2.2 (Feb 28, 2022)
  - revised output of `GxB*_sort` to return newly created matrices `C` and `P` as full or bitmap matrices, as appropriate, instead of sparse/hypersparse, following their sparsity control settings.
- Version 6.2.1 (Feb 14, 2022)
  - (41) bug fix: `GxB_Iterator_get` used `(void *) + size` arithmetic
- Version 6.2.0 (Feb 14, 2022)
  - added the `GxB_Iterator` object and its methods. See Section 14.
  - `@GrB` interface: revised sparse-times-full rule for the conventional semiring (the syntax `C=A*B`), so that sparse-times-full results in `C` as full, but hypersparse-times-sparse is not full (typically sparse or hypersparse).
- Version 6.1.4 (Jan 12, 2022)
  - added Section 16 to User Guide: how to get the best performance out of algorithms based on GraphBLAS.
  - `cpu_features`: no longer built as a separate library, but built directly into `libgraphblas.so` and `libgraphblas.a`. Added compile-time flags to optionally disable the use of `cpu_features` completely.
  - Octave 7: port to Apple Silicon (thanks to Gábor Szárnyas).
  - min/max monoids: real case (FP32 and FP64) no longer terminal
  - `@GrB` interface: overloaded `C=A*B` syntax where one matrix is full always results in a full matrix `C`.
  - Faster `C=A*B` for sparse-times-full and full-times-sparse for `@GrB` interface.
- Version 6.1.3 (Jan 1, 2022)

- performance: task creation for `GrB_mxm` had a minor flaw (results were correct but parallelism suffered). Performance improvement of up to 10x when `nnz(A) > nnz(B)`.
- Version 6.1.2 (Dec 31, 2021)
  - performance: revised `swap_rule` in `GrB_mxm`, which decides whether to compute  $C=A*B$  or  $C=(B'*A')'$ , and variants, resulting in up to 3x performance gain over v6.1.1 for `GrB_mxm` (observed; could be higher in other cases).
- Version 6.1.1 (Dec 28, 2021)
  - minor revision to AVX2 and AVX512f selection
  - `cpu_features/Makefile`: remove test of `list_cpu_features` so that the package can be built when cross-compiling
- Versions 6.1.0 (Dec 26, 2021)
  - added `GxB_get` options: compiler name and version.
  - added package: [https://github.com/google/cpu\\_features](https://github.com/google/cpu_features), Nov 30, 2021 version.
  - performance: faster  $C+=A*B$  when  $C$  is full,  $A$  is bitmap/full, and  $B$  is sparse/hyper. Faster  $C+=A'*B$  when  $A$  is sparse/hyper, and  $B$  is bitmap/full.
  - (40) bug fix: deserialization of iso and empty matrices/vectors was incorrect
- Versions 6.0.2 and 5.2.2 (Nov 30, 2021)
  - (39) bug fix: `GrB_Matrix_export`: numerical values not properly exported
- Versions 6.0.1 and 5.2.1 (Nov 27, 2021)
  - v6.0.x and v5.2.x (for the same x): differ only in `GrB_wait`, `GrB_Info`, `GrB_SCMP`, and `GxB_init`.

- (38) bug fix: `C+=A'*B` when the accum operator is the same as the monoid and `C` is iso-full, and `A` or `B` are hypersparse. (dot4 method).
  - performance: `GrB_select` with user-defined `GrB_IndexUnaryOp` about 2x faster.
  - performance: faster `(MIN,MAX)_(FIRSTJ,SECONDI)` semirings
- Version 6.0.0 (Nov 15, 2021)
    - this release contains only a few changes that cause a break with backward compatibility. It is otherwise identical to v5.2.0.
    - v6.0.0 is fully compliant with the v2.0 C API Specification. Three changes from the v2.0 C API Spec are not backward compatible (`GrB_*wait`, `GrB_Info`, `GrB_SCMP`). `GxB_init` has also changed.
      - \* `GrB_wait (object, mode)`: was `GrB_wait (&object)`.
      - \* `GrB_Info`: changed enum values
      - \* `GrB_SCMP`: removed
      - \* `GxB_init (mode, malloc, calloc, realloc, free, is_thread_safe)`: the last parameter, `is_thread_safe`, is deleted. The `malloc`, `calloc`, `realloc`, and `free` functions must be thread-safe.
  - Version 5.2.0 (Nov 15, 2021)
    - Added for the v2.0 C API Specification: only features that are backward compatible with SuiteSparse:GraphBLAS v5.x have been added to v5.2.0:
      - \* `GrB_Scalar`: replaces `GxB_Scalar`, `GxB_Scalar_*` functions renamed `GrB`
      - \* `GrB_IndexUnaryOp`: new, `free`, `fprint`, `wait`
      - \* `GrB_select`: selection via `GrB_IndexUnaryOp`
      - \* `GrB_apply`: with `GrB_IndexUnaryOp`
      - \* `GrB_reduce`: reduce matrix or vector to `GrB_Scalar`
      - \* `GrB_assign`, `GrB_subassign`: with `GrB_Scalar` input
      - \* `GrB_*_extractElement_Scalar`: get `GrB_Scalar` from a matrix or vector
      - \* `GrB*build`: when `dup` is `NULL`, duplicates result in an error.

- \* `GrB_import/export`: import/export from/to user-provided arrays
- \* `GrB_EMPTY_OBJECT`, `GrB_NOT_IMPLEMENTED`: error codes added
- \* `GrB*_setElement_Scalar`: set an entry in a matrix or vector, from a `GrB_Scalar`
- \* `GrB_Matrix_diag`: same as `GxB_Matrix_diag (C,v,k,NULL)`
- \* `GrB*_serialize/deserialize`: with compression
- \* `GrB_ONEB_T`: binary operator,  $f(x,y) = 1$ , the same as `GxB_PAIR_T`.
- `GxB*import*` and `GxB*export*`: now historical.
- `GxB_select`: is now historical; use `GrB_select` instead.
- `GxB_IGNORE_DUP`: special operator for build methods only; if dup is this operator, then duplicates are ignored (not an error)
- `GxB_IndexUnaryOp_new`: create a named index-unary operator
- `GxB_BinaryOp_new`: create a named binary operator
- `GxB_UnaryOp_new`: create a named unary operator
- `GxB_Type_new`: to create a named type
- `GxB_Type_name`: to query the name of a type
- added `GxB*_type_name` methods to query the name of a type as a string.
- `GxB_Matrix_serialize/deserialize`: with compression; optional descriptor.
- `GxB_Matrix_sort`, `GxB_Vector_sort`: sort a matrix or vector
- `GxB_eWiseUnion`: like `GrB_eWiseAdd` except for how entries in  $\mathbf{A} \setminus \mathbf{B}$  and  $\mathbf{B} \setminus \mathbf{A}$  are computed.
- added LZ4/LZ4HC: compression library, <http://www.lz4.org> (BSD 2), v1.9.3, Copyright (c) 2011-2016, Yann Collet.
- MIS and pagerank demos: removed; MIS added to LAGraph/experimental
- disabled free memory pool if OpenMP not available
- (37) bug fix: ewise  $\mathbf{C}=\mathbf{A}+\mathbf{B}$  when all matrices are full, `GBCOMPACT` not used, but `GB_control.h` disabled the operator or type. Caught by Roi Lipman, Redis.
- (36) bug fix:  $\mathbf{C}<\mathbf{M}>=\mathbf{Z}$  not returning  $\mathbf{C}$  as iso if  $\mathbf{Z}$  iso and  $\mathbf{C}$  initially empty. Caught by Erik Welch, Anaconda.
- performance improvements:  $\mathbf{C}=\mathbf{A}*\mathbf{B}$ : sparse/hyper times bitmap/full, and visa versa, including  $\mathbf{C} += \mathbf{A}*\mathbf{B}$  when  $\mathbf{C}$  is full.

- Version 5.1.10 (Oct 27, 2021)
  - (35) bug fix: `GB_selector`; `A->plen` and `C->plen` not updated correctly. Caught by Jeffry Lovitz, Redis.
- Version 5.1.9 (Oct 26, 2021)
  - (34) bug fix: in-place test incorrect for `C+=A'*B` using dot4
  - (33) bug fix: disable free pool if OpenMP not available
- Version 5.1.8 (Oct 5, 2021)
  - (32) bug fix: `C=A*B` when A is sparse and B is iso and bitmap. Caught by Mark Blanco, CMU.
- Version 5.1.7 (Aug 23, 2021)
  - (31) bug fix: `GrB_apply`, when done in-place and matrix starts non-iso and becomes iso, gave the wrong iso result. Caught by Fabian Murariu.
- Version 5.1.6 (Aug 16, 2021)
  - one-line change to `C=A*B`: faster symbolic analysis when a vector `C(:,j)` is dense (for CSC) or `C(i,:)` for CSR.
- Version 5.1.5 (July 15, 2021)
  - submission to ACM Transactions on Mathematical Software as a Collected Algorithm of the ACM.
- Version 5.1.4 (July 6, 2021)
  - faster Octave interface. Octave v7 or later is required.
  - (30) bug fix: 1-based printing not enabled for pending tuples. Caught by Will Kimmerer, while working on the Julia interface.
- Version 5.1.3 (July 3, 2021)

- added `GxB_Matrix_iso` and `GxB_Vector_iso`: to query if a matrix or vector is held as iso-valued
  - (29) bug fix: `Matrix_pack*R` into a matrix previously held by column, or `Matrix_pack*C` into a matrix by row, would flip the dimensions. Caught by Erik Welch, Anaconda.
  - (28) bug fix: `kron(A,B)` with iso input matrices `A` and `B` fixed. Caught by Michel Pelletier, Graphegon.
  - (27) bug fix: v5.1.0 had a wrong version of a file; posted by mistake. Caught by Michel Pelletier, Graphegon.
- Version 5.1.2 (June 30, 2021)
    - iso matrices added: these are matrices and vectors whose values in the sparsity pattern are all the same. This is an internal change to the opaque data structures of the `GrB_Matrix` and `GrB_Vector` with very little change to the API.
    - added `GxB_Matrix_build_Scalar` and `GxB_Vector_build_Scalar`, which always build iso matrices and vectors.
    - import/export methods can now import/export iso matrices and vectors.
    - added `GrB.argmaxin/argmax` to MATLAB/Octave interface
    - added `GxB*_pack/unpack` methods in place of import/export.
    - added `GxB_PRINT_1BASED` to the global settings.
    - added `GxB*_memoryUsage`
    - port to Octave: `gbmake` and `gbtest` work in Octave7 to build and test the `@GrB` interface to GraphBLAS. Octave 7.0.0 is required.
  - Version 5.0.6 (May 24, 2021)
    - BFS and triangle counting demos removed from GraphBLAS/Demo: see LAGraph for these algorithms. Eventually, all of GraphBLAS/Demo will be deleted, once LAGraph includes all the methods included there.
  - Version 5.0.5 (May 17, 2021)
    - (26) performance bug fix: reduce-to-vector where `A` is hypersparse CSR with a transposed descriptor (or CSC with no transpose),

and some cases for `GrB_mxm/mxv/vxm` when computing  $C=A*B$  with A hypersparse CSC and B bitmap/full (or A bitmap/full and B hypersparse CSR), the wrong internal method was being selected via the auto-selection strategy, resulting in a significant slowdown in some cases.

- Version 5.0.4 (May 13, 2021)
  - @GrB MATLAB/Octave interface: changed license to GNU General Public License v3.0 or later. It was licensed under Apache-2.0 in Version 5.0.3 and earlier. Changed back to Apache-2.0 for Version 7.3.0; see above.
- Version 5.0.3 (May 12, 2021)
  - (25) bug fix: disabling `ANY_PAIR` semirings by editing `Source/GB_control.h` would cause a segfault if those disabled semirings were used.
  - demos are no longer built by default
  - (24) bug fix: new functions in v5.0.2 not declared as `extern` in `GraphBLAS.h`.
  - `GrB_Matrix_reduce_BinaryOp` reinstated from v4.0.3; same limit on built-in ops that correspond to known monoids.
- Version 5.0.2 (May 5, 2021)
  - (23) bug fix: `GrB_Matrix_apply_BinaryOp1st` and `2nd` were using the wrong descriptors for `GrB_INP0` and `GrB_INP1`. Caught by Erik Welch, Anaconda.
  - memory pool added for faster allocation/free of small blocks
  - @GrB interface ported to MATLAB R2021a.
  - `GxB_PRINTF` and `GxB_FLUSH` global options added.
  - `GxB_Matrix_diag`: construct a diagonal matrix from a vector
  - `GxB_Vector_diag`: extract a diagonal from a matrix
  - `concat/split`: methods to concatenate and split matrices.
  - `import/export`: size of arrays now in bytes, not entries. This change is required for better internal memory management, and it is not backward compatible with the `GxB*import/export` functions in v4.0. A new parameter, `is_uniform`, has been added to

all import/export methods, which indicates that the matrix values are all the same.

- (22) bug fix: SIMD vectorization was missing `reduction(+,task_cnvals)` in `GB_dense_subassign_06d_template.c`. Caught by Jeff Huang, Texas A&M, with his software package for race-condition detection.
- `GrB_Matrix_reduce_BinaryOp`: removed. Use a monoid instead, with `GrB_reduce` or `GrB_Matrix_reduce_Monoid`.

- Version 4.0.3 (Jan 19, 2021)

- faster min/max monoids
- `G=GrB(G)` converts `G` from v3 object to v4

- Version 4.0.2 (Jan 13, 2021)

- ability to load `*.mat` files saved with the v3 `GrB`

- Version 4.0.1 (Jan 4, 2021)

- significant performance improvements: compared with v3.3.3, up to 5x faster in breadth-first-search (using `LAGraph_bfs_parent2`), and 2x faster in Betweenness-Centrality (using `LAGraph_bc_batch5`).
- `GrB_wait(void)`, with no inputs: removed
- `GrB_wait(&object)`: polymorphic function added
- `GrB*_nvals`: no longer guarantees completion; use `GrB_wait(&object)` or non-polymorphic `GrB*_wait (&object)` instead
- `GrB_error`: now has two parameters: a string (`char **`) and an object.
- `GrB_Matrix_reduce_BinaryOp` limited to built-in operators that correspond to known monoids.
- `GrB*_extractTuples`: may return indices out of order
- removed internal features: GBI iterator, slice and hyperslice matrices
- bitmap/full matrices and vectors added
- index-based operators and semirings: `GxB_FIRSTI_INT32` and related ops

- jumbled matrices: sort left pending, like zombies and pending tuples
  - `GxB_get/set`: added `GxB_SPARSITY_*` (hyper, sparse, bitmap, or full) and `GxB_BITMAP_SWITCH`.
  - `GxB_HYPER`: enum renamed to `GxB_HYPER_SWITCH`
  - `GxB*import/export`: API modified
  - `GxB_SelectOp`: `nrows` and `ncols` removed from function signature.
  - OpenMP tasking removed from mergesort and replaced with parallel for loops. Just as fast on Linux/Mac; now the performance ports to Windows.
  - `GxB_BURBLE` added as a supported feature. This was an undocumented feature of prior versions.
  - bug fix: `A({lo,hi})=scalar` `A(lo:hi)=scalar` was OK
- Version 3.3.3 (July 14, 2020). Bug fix: `w<m>=A*u` with mask non-empty and `u` empty.
  - Version 3.3.2 (July 3, 2020). Minor changes to build system.
  - Version 3.3.1 (June 30, 2020). Bug fix to `GrB_assign` and `GxB_subassign` when the assignment is simple (`C=A`) but with typecasting.
  - Version 3.3.0 (June 26, 2020). Compliant with V1.3 of the C API (except that the polymorphic `GrB_wait(&object)` doesn't appear yet; it will appear in V4.0).

Added complex types (`GxB_FC32` and `GxB_FC64`), many unary operators, binary operators, monoids, and semirings. Added bitwise operators, and their monoids and semirings. Added the predefined monoids and semirings from the v1.3 specification. `@GrB` interface: added complex matrices and operators, and changed behavior of integer operations to more closely match the behavior on built-in integer matrices. The rules for typecasting large floating point values to integers has changed. The specific object-based `GrB_Matrix_wait`, `GrB_Vector_wait`, etc, functions have been added. The no-argument `GrB_wait()` is deprecated. Added `GrB_getVersion`, `GrB_Matrix_resize`, `GrB_Vector_resize`, `GrB_kronecker`, `GrB_*_wait`, scalar binding with binary operators for

`GrB_apply`,  
`GrB_Matrix_removeElement`, and `GrB_Vector_removeElement`.

- Version 3.2.0 (Feb 20, 2020). Faster `GrB_mxm`, `GrB_m xv`, and `GrB_vxm`, and faster operations on dense matrices/vectors. Removed compile-time user objects (`GxB*_define`), since these were not compatible with the faster matrix operations. Added the `ANY` and `PAIR` operators. Added the predefined descriptors, `GrB_DESC_*`. Added the structural mask option. Changed default chunk size to 65,536. `@GrB` interface modified: `GrB.init` is now optional.
- Version 3.1.2 (Dec, 2019). Changes to allow SuiteSparse:GraphBLAS to be compiled with the Microsoft Visual Studio compiler. This compiler does not support the `_Generic` keyword, so the polymorphic functions are not available. Use the equivalent non-polymorphic functions instead, when compiling GraphBLAS with MS Visual Studio. In addition, variable-length arrays are not supported, so user-defined types are limited to 128 bytes in size. These changes have no effect if you have an C11 compliant compiler.  
`@GrB` interface modified: `GrB.init` is now required.
- Version 3.1.0 (Oct 1, 2019). `@GrB` interface added. See the `GraphBLAS/GraphBLAS` folder for details and documentation, and Section [4.1](#).
- Version 3.0 (July 26, 2019), with OpenMP parallelism.

The version number is increased to 3.0, since this version is not backward compatible with V2.x. The `GxB_select` operation changes; the `Thunk` parameter was formerly a `const void *` pointer, and is now a `GxB_Scalar`. A new parameter is added to `GxB_SelectOp_new`, to define the expected type of `Thunk`. A new parameter is added to `GxB_init`, to specify whether or not the user-provided memory management functions are thread safe.

The remaining changes add new features, and are upward compatible with V2.x. The major change is the addition of OpenMP parallelism. This addition has no effect on the API, except that round-off errors can differ with the number of threads used, for floating-point types. `GxB_set` can optionally define the number of threads to use

(the default is `omp_get_max_threads`). The number of threads can also be defined globally, and/or in the `GrB_Descriptor`. The `RDIV` and `RMINUS` operators are added, which are defined as  $f(x, y) = y/x$  and  $f(x, y) = y - x$ , respectively. Additional options are added to `GxB_get`.

- Version 2.3.3 (May 2019): Collected Algorithm of the ACM. No changes from V2.3.2 other than the documentation.
- Version 2.3 (Feb 2019) improves the performance of many GraphBLAS operations, including an early-exit for monoids. These changes have a significant impact on breadth-first-search (a performance bug was also fixed in the two BFS `Demo` codes). The matrix and vector import/export functions were added, in support of the new LAGraph project (<https://github.com/GraphBLAS/LAGraph>, see also Section 17.1). LAGraph includes a push-pull BFS in GraphBLAS that is faster than two versions in the `Demo` folder. `GxB_init` was added to allow the memory manager functions (`malloc`, etc) to be specified.
- Version 2.2 (Nov 2018) adds user-defined objects at compile-time, via user `*.m4` files placed in `GraphBLAS/User`, which use the `GxB_*_define` macros (NOTE: feature removed in v3.2). The default matrix format is now `GxB_BY_ROW`. Also added are the `GxB_*print` methods for printing the contents of each GraphBLAS object (Section 13). PageRank demos have been added to the `Demos` folder.
- Version 2.1 (Oct 2018) was a major update with support for new matrix formats (by row or column, and hypersparse matrices), and colon notation (`I=begin:end` or `I=begin:inc:end`). Some graph algorithms are more naturally expressed with matrices stored by row, and this version includes the new `GxB_BY_ROW` format. The default format in Version 2.1 and prior versions is by column. New extensions to GraphBLAS in this version include `GxB_get`, `GxB_set`, and `GxB_AxB_METHOD`, `GxB_RANGE`, `GxB_STRIDE`, and `GxB_BACKWARDS`, and their related definitions, described in Sections 6.16, 10, and 11.
- Version 2.0 (March 2018) addressed changes in the GraphBLAS C API Specification and added `GxB_kron` and `GxB_resize`.
- Version 1.1 (Dec 2017) primarily improved the performance.
- Version 1.0 was released on Nov 25, 2017.

## 19.1 Regarding historical and deprecated functions and symbols

When a **GxB\*** function or symbol is added to the C API Specification with a **GrB\*** name, the new **GrB\*** name should be used instead, if possible. However, the old **GxB\*** name will be kept as long as possible for historical reasons. Historical functions and symbols will not always be documented here in the SuiteSparse:GraphBLAS User Guide, but they will be kept in **GraphbBLAS.h** and kept in good working order in the library. Historical functions and symbols would only be removed in the very unlikely case that they cause a serious conflict with future methods.

The following methods have been fully deprecated and removed. The older versions of **GrB\_wait** and **GrB\_error** methods have been removed since they are incompatible with the latest versions, per the C API Specification. The **GxB\_SelectOp\_new** and **GxB\_SelectOp\_free** methods have been removed, and some of the built-in operators have been revised (specifically, the **GxB\_EQ\_THUNK**, **GxB\_EQ\_ZERO**, **GxB\_NE\_THUNK**, and **GxB\_NE\_ZERO** operators no longer work on user-defined types).

## 20 Acknowledgments

I would like to thank Jeremy Kepner (MIT Lincoln Laboratory Supercomputing Center), and the GraphBLAS API Committee: Aydın Buluç (Lawrence Berkeley National Laboratory), Timothy G. Mattson (Intel Corporation) Scott McMillan (Software Engineering Institute at Carnegie Mellon University), José Moreira (IBM Corporation), Carl Yang (UC Davis), and Benjamin Brock (UC Berkeley), for creating the GraphBLAS specification and for patiently answering my many questions while I was implementing it.

I would like to thank Tim Mattson and Henry Gabb, Intel, Inc., for their collaboration and for the support of Intel.

I would like to thank Joe Eaton and Corey Nolet for their collaboration on the CUDA kernels (still in progress), and for the support of NVIDIA.

I would like to thank Pat Quillen for his collaboration and for the support of MathWorks.

I would like to thank John Eaton for his collaboration on the integration with Octave 7.

I would like to thank Michel Pelletier for his collaboration and work on

the pygraphblas interface, and Jim Kitchen and Erik Welch for their work on Anaconda’s python interface.

I would like to thank Will Kimmerer for his collaboration and work on the Julia interface.

I would like to thank John Gilbert (UC Santa Barbara) for our many discussions on GraphBLAS, and for our decades-long conversation and collaboration on sparse matrix computations.

I would like to thank Sébastien Villemot (Debian Developer, <http://sebastien.villemot.name>) for helping me with various build issues and other code issues with GraphBLAS (and all of SuiteSparse) for its packaging in Debian Linux.

I would like to thank Gábor Szárnyas for porting the @GrB interface to Octave 7 on Apple Silicon.

I would like to thank Markus Mützel for his help in porting the updates to GraphBLAS v7.4.1 and SuiteSparse v7.0.0 to Windows.

I would like to thank Roi Lipman, Redis (<https://falkordb.com>), for our many discussions on GraphBLAS and for enabling its use in RedisGraph and FalkorDB, a graph database module for Redis. Based on SuiteSparse:GraphBLAS, FalkorDB is up 600x faster than the fastest graph databases (<https://youtu.be/9h3Qco.x0QE> <https://redislabs.com/blog/new-redisgraph-1-0-achieves-600x-faster-performance-graph-databases/>).

SuiteSparse:GraphBLAS was developed with support from NVIDIA, Intel, MIT Lincoln Lab, MathWorks, Redis, FalkorDB, IBM, the National Science Foundation (1514406, 1835499), and Julia Computing.

## 21 Additional Resources

See <http://graphblas.org> for the GraphBLAS community page. See <https://github.com/GraphBLAS/GraphBLAS-Pointers> for an up-to-date list of additional resources on GraphBLAS, maintained by Gábor Szárnyas.

From the preface: Graphs are among the most important abstract data types in computer science, and the algorithms that operate on them are critical to modern life. Graphs have been shown to be powerful tools for modeling complex problems because of their simplicity and generality. Graph algorithms are one of the pillars of mathematics, informing research in such diverse areas as combinatorial optimization, complexity theory, and topology. Algorithms on graphs are applied in many ways in today’s world – from Web rankings to metabolic networks, from finite element meshes to semantic graphs. The current exponential growth in graph data has forced a shift to parallel computing for executing graph algorithms. Implementing parallel graph algorithms and achieving good parallel performance have proven difficult. This book addresses these challenges by exploiting the well-known duality between a canonical representation of graphs as abstract collections of vertices and edges and a sparse adjacency matrix representation. This linear algebraic approach is widely accessible to scientists and engineers who may not be formally trained in computer science. The authors show how to leverage existing parallel matrix computation techniques and the large amount of software infrastructure that exists for these computations to implement efficient and scalable parallel graph algorithms. The benefits of this approach are reduced algorithmic complexity, ease of implementation, and improved performance. DOI: <https://dx.doi.org/10.1137/1.9780898719918>
